

Sorting Algorithm

Examples of well-known algorithms

Goal

- Understand well-known algorithm
- Can write a working program of the algorithms
- Can analyze it

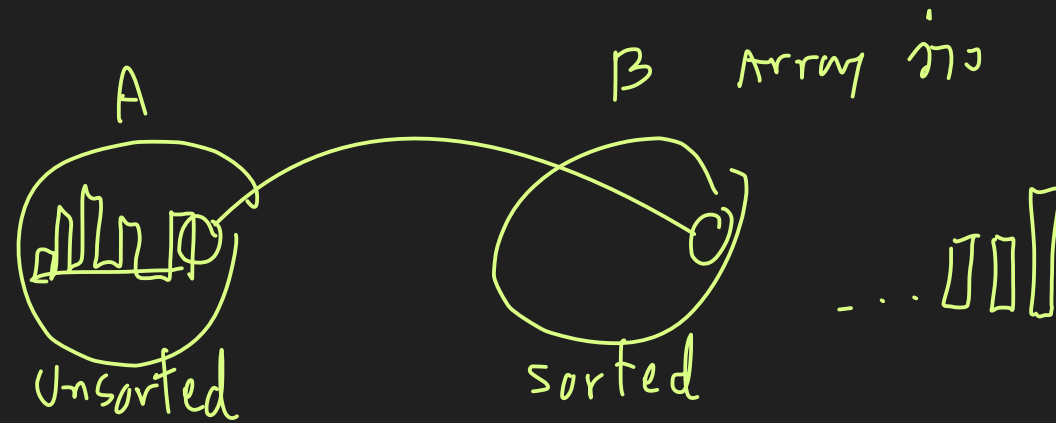

Problem

- Input:
 - Array $A[1..n]$ of n data (we must be able to compare a pair of them)
- Output:
 - The same array but re-arranged such that $A[i] \leq A[i+1]$ for every i from 1 to $N-1$
- Example instance
 - Input: [1,5,3,2,7,1]
 - Output: [1,1,2,3,5,7]

Several Algorithms

Algorithm	Complexity
→ Bubble Sort (not-covered in this class)	$O(n^2)$ ไม่ค่อยนิยม, อริทเมติก
① → Selection Sort variation: Heap Sort ←	$\Theta(n^2)$ $O(n \lg n)$
② → Insertion Sort variation: <u>Shellsort</u>	$O(n^2)$?
→ Radix Sort (already covered in Data Structure)	$O(N)$ จัดเรียงไม่ทุกประเภท เรียงกัน เป็นหลัก
Merge Sort (will be on D&C topics)	$O(n \lg n)$
Quick Sort (will be on D&C topics)	$O(n^2)$ (on average $O(n \log n)$)

Selection Sort

- Key Idea:
 - There are two parts of data: **Unsorted array** and **Sorted array**
 - Start by let the input be the unsorted array
 - let sorted array be an empty array
 - While the unsorted array is not empty
 - Get the maximum one
 - Put it at the front of the sorted array
 - Delete it from the unsorted array

Example pseudo code

```
#input: array A[1..n]
def selection_sort
  let B be an empty array
  while A is not empty
    #find the index of maximum item
    max_idx = 1
    for i = 1 to sizeof(A)
      if A[i] > A[max_idx]
        max_idx = i

    #move the maximum element
    insert A[max_idx] at the front of B
    remove item at position max_idx from A
  return B
```

Handwritten notes in Thai:

- max_idx (with arrow pointing to the variable)
- ใน i เป็น index ของตัวที่มากที่สุด (i is the index of the largest element)
- นำค่า (bring the value)

What is the drawback of this pseudo code?

นิยมใช้สลับความ (usually used to swap)

①

Can we convert it to a working C++?

How is the time complexity?

Example Code

```
template<typename T>
vector<T> selection_sort(vector<T> A) {
    vector<T> B;
    while (A.size() > 0) {
        auto it = max_element(A.begin(), A.end());
        B.insert(B.begin(), *it);       $O(N)$ 
        A.erase(it);                   $O(N)$ 
    }
    return B;
}
```

```
template<typename T>
vector<T> selection_sort(vector<T> A) {
    vector<T> B(A.size()); จะรองรับไว้แล้ว a: ได้โดยไม่ต้อง ensure capacity
    while (A.size() > 0) {
        auto it = max_element(A.begin(), A.end());
        B[A.size() - 1] = *it;       $O(1)$ 
        swap(*it, A[A.size() - 1]);  $O(1)$ 
        A.pop_back();               $O(1)$ 
    }
    return B;
}
```

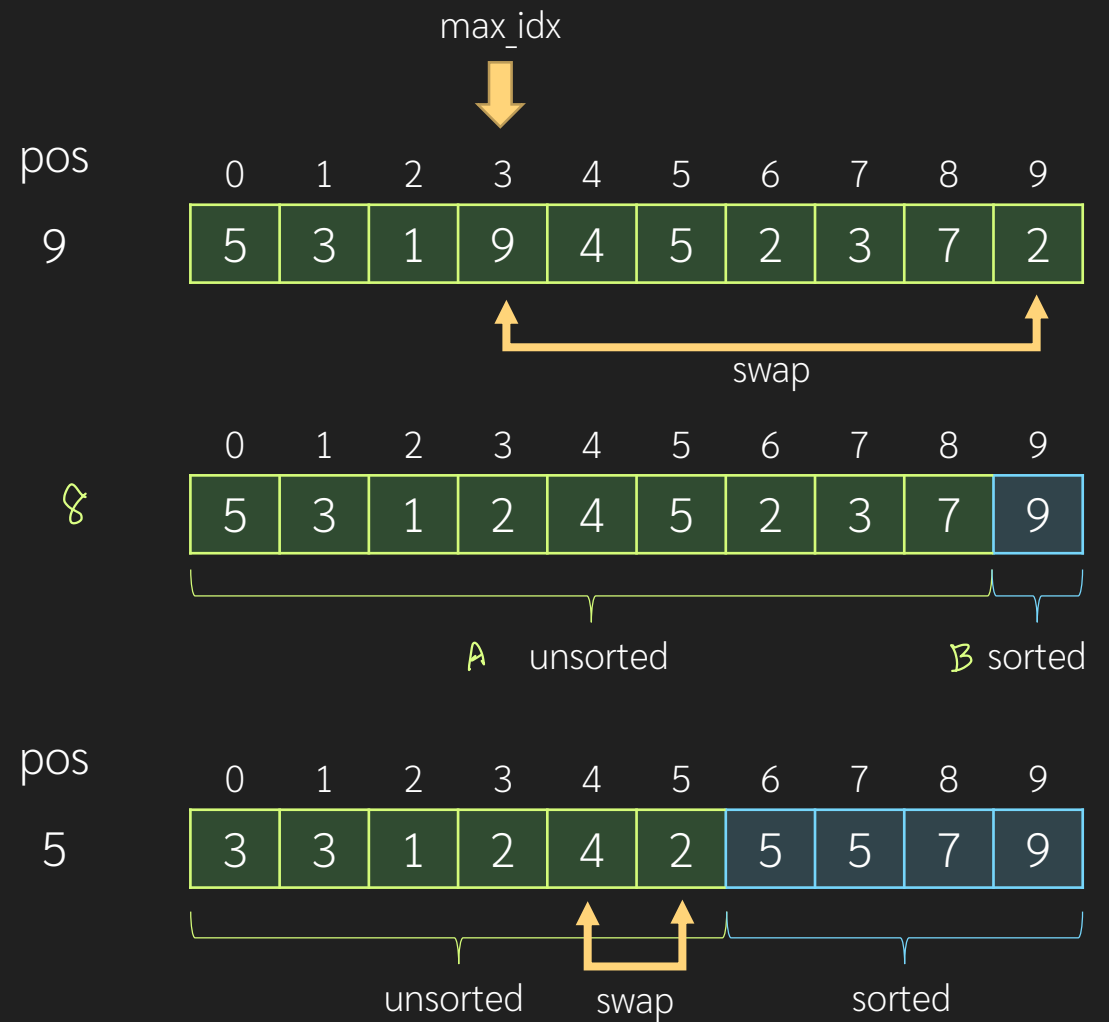

Which one is faster?

Actual Code

A | | B

```
template<typename T>
void selection_sort(vector<T> &A) {
    size_t pos = A.size()-1;
    for ( ; pos > 0; pos--) {
        int max_idx = 0;
        for (size_t i = 0; i <= pos; i++) {
            if (A[i] > A[max_idx]) {
                max_idx = i;
            }
        }
        swap(A[target_pos], A[max_idx]);
    }
}
```

- In-place swap
 - Does not need another vector
 - $O(1)$ in swap

Complexity Analysis

pseudo

```
#input: array A[1..n]
def selection_sort
  pos = n
  while pos > 1
    #find the index of maximum item
    max_idx = 1
    for i = 1 to pos          n
      if A[i] > A[max_idx]    n-1
        max_idx = i          n-2

    #swap the maximum element
    swap(A[max_idx], A[pos])
    pos = pos - 1
  return A
```

- While-loop runs $n-1$ times
- In each loop, the for-loop runs pos times
- $T(n) = n + n-1 + n-2 + \dots + 2$
- $T(n) = \underline{\Theta(n^2)}$

Selection Sort variation: Heap Sort

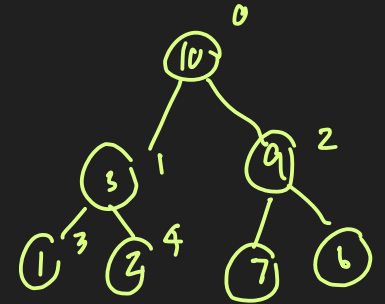

- Improve finding max element by using Binary Heap

- Key Idea:

- Treat **unsorted** portion of the array as a **binary heap**
 - We can find max and remove very fast
- At start, we **build_heap** ($O(n)$) on the unsorted array
 - Build heap = **fix_down** on $n/2$ to 1
- For each iteration, assume that the heap is at **$A[1..pos]$**
 - the maximum element in $[1..pos]$ is at **$A[1]$**
 - Do Binary Heap's **pop**, which is swapping **$A[1]$** with **$A[pos]$** and **fix_down** (same thing as we want)

full bi tree

Heap Sort

(A, pos)

if (pos == 1) return
else swap (A[1], A[pos])

fix_down (A, 1, pos)
~~~~~  
(A, pos)

```
#input: array A[1..n]
```

```
def heap_sort(A)
```

```
    pos = n
```

```
    for i = n/2 to 1
```

```
        #fix_down will perform heap's fix_down at position i
```

```
        # assuming the heap is in the array A[1..pos]
```

```
        fix_down(A, i, pos);
```

```
    while pos > 1
```

```
        swap(A[1], A[pos])
```

```
        pos = pos - 1
```

```
        fix_down(A, 1, pos);
```

```
    return A
```

```
#input: A = array A
```

```
#input: i is the position to fix down
```

```
#input: size is the size of heap in A (A[1..size])
```

```
def fix_down(A, i, size)
```

```
    tmp = A[i];
```

```
    while ((c = 2 * i + 1) < size)
```

```
        if (c + 1 <= size && A[c] < A[c+1]) c++;
```

```
        if (A[c] < tmp) break;
```

```
        A[i] = A[c];
```

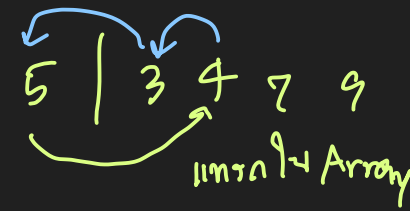

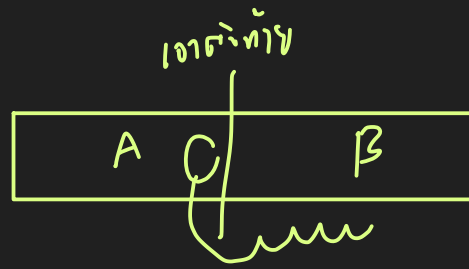

```
        i = c;
```

```
    A[i] = tmp
```

# Heap Sort Analysis

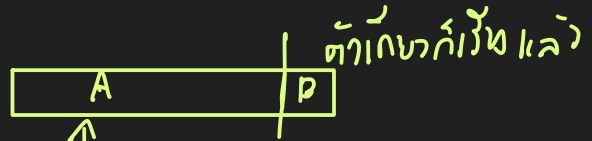

- `build_heap` requires  $O(N)$ 
  - As we have learned from `priority_queue` in our Data Structure class
- There is  $n-1$  iterations of the while loop
  - Each loop is basically `pop()` operation of the binary heap which is  $O(\lg n)$
- This total to  $O(n \log n)$

# Insertion Sort

- Key Idea:
  - Maintain two-parts of the input array, **unsorted** and **sorted** part, similar to the actual version of the selection sort
  - In each iteration, instead of identifying the maximum element in the unsorted part and prepend it to the sorted part
    - Insertion sort try to **insert the last element of the unsorted part** to the **sorted part** so that the new element is at the correct position (making the sorted list still sorted)

# Pseudo-code

```
#input: array A[1..n]
def insertion_sort
  pos = n-1
  while pos > 0
    #find minimum i in the range [pos+1..n] such that
    #  A[pos] <= A[i]
    #  if no such i exists, let i be n
    i = pos+1
    while (i <= n && A[pos] > A[i])
      i = i + 1
    #insert A[pos] after A[i]
    j = pos
    tmp = A[pos]
    while (j < i)
      A[j] = A[j+1];
      j = j + 1
    A[i] = tmp
  pos = pos - 1
```

100 | 2 3 9 20

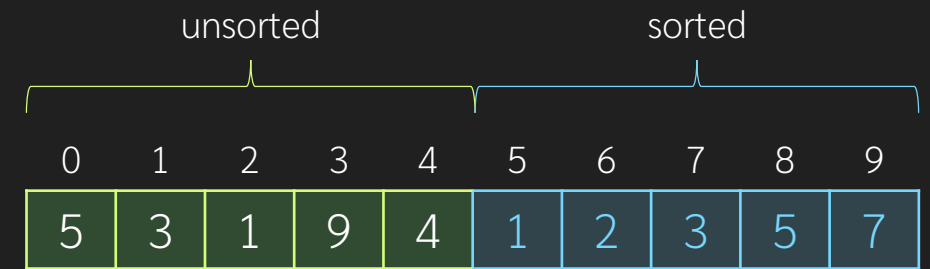

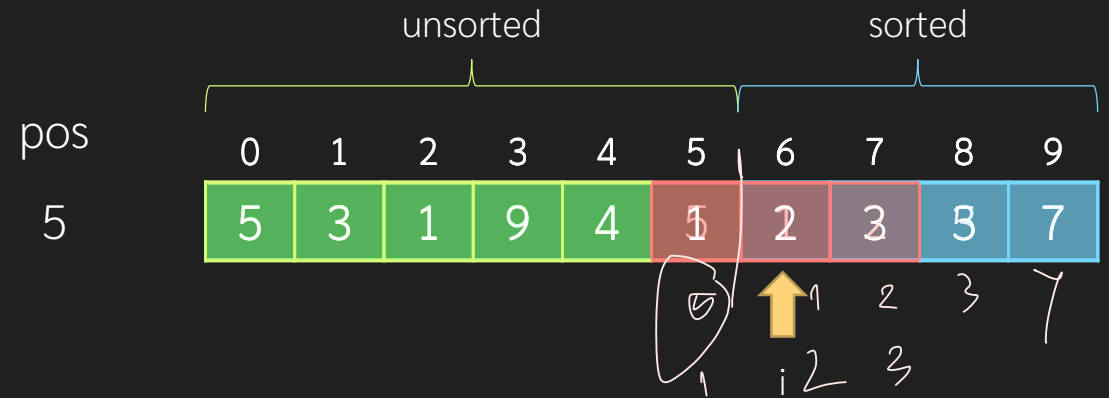

before

function insert vector

# Actual Code မှည့်ကုန်မယူ + အလုပ်ဖြစ်မယ့်

```
template <typename T>
void insertion_sort(vector<T> &A) {
    for (int pos = A.size()-2; pos >= 0; pos--) {
        T tmp = A[pos];
        size_t i = pos+1;
        while (i < A.size() && A[i] < tmp) {
            A[i-1] = A[i];
            i++;
        }
        A[i-1] = tmp;
    }
}
```

- Find and insert simultaneously

# Analysis

$A[i] > 0$

$val > 0$

$O(N)$

```
template <typename T>
void insertion_sort(vector<T> &A) {
    for (int pos = A.size()-2; pos >= 0; pos--) {
        T tmp = A[pos];
        size_t i = pos+1;
        while (i < A.size() && A[i] < tmp) {
            A[i-1] = A[i];
            i++;
        }
        A[i-1] = tmp;
    }
}
```

nest  $O(N)$

Insertion Sort is  $O(N^2)$

- For loop N-1 iteration
- Each for loop perform at most (pos-1)
- $T(N) = \underline{1+2+3+\dots+N-1}$
- It is possible that  $\underline{T(N) = 1+1+1+\dots+1}$ 
  - When?

```
for (int pos = r - 1; pos >= 0; pos--) {
    T tmp = A[pos];
    size_t i = pos + 1;
    while (i < A.size() && A[i] < tmp) {
        A[i-1] = A[i];
        i++;
    }
    A[i-1] = tmp;
}
```

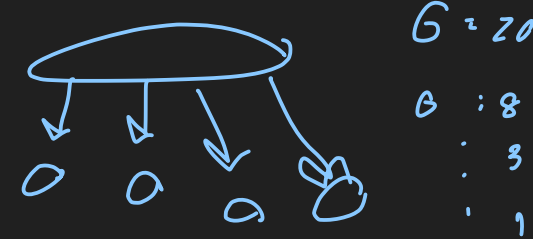

# Analysis of insertion sort

- On each iterations, insertion sorts try to insert  $A[pos]$  to its correct position
  - If the correct position of  $A[pos]$  is far from pos, we need to move it that much
- If we can quickly identify the correct position of  $A[pos]$ , we still need to move that many elements because of insert
- When the input is *almost sorted*, i.e., their elements does not stay away from its correct position, *insertion sort works fast*
  - For example [1, 2, 3, 2, 4, 7, 5, 6]

# Insertion Sort variation: Shellsort

- Invented by Donald shell *ดอนัลด์*  $G = 20$
- Key Idea:
  - Start by letting  $G$  = some large value less than  $N$  and doing these process
    - (a) Divide  $A$  into  $G$  smaller arrays, each consist of element in  $A$  that is  $G$  elements apart
    - (b) Sort each sub-array by insertion sort
  - Repeat (a) and (b) with smaller value of  $G$ 
    - Keep doing (a) and (b) until  $G$  is 1 *in 1s*
    - When  $G = 1$  it is basically the insertion sort but the array should be almost sorted
- It is like trying to move each element to its correct position faster
- Sequence of  $G$  is important

## Example when $G = 4$

(a) Divide into 4 groups

(b) Sort each group

အသေးစဉ်အသေးစဉ်

1 4 2 6 1 8 3 6 7 9

Do it again with  $G = 2$

1 4 2 6 1 8 3 6 7 9

1 1 2 3 7

4 6 6 8 9

1 4 1 6 2 6 3 8 7 9

Do it again with  $G = 1$

รวมชุดที่  
กระโดดโดดเดี่ยว

# Pseudo-code

```
#input: array A[1..n]
def shell_sort
  gaps = [701,301,132,57,23,10,4,1]
  for G in gaps
    #for each value of G, we do G groups
    ✓ for round = n downto n-gap+1
      #in each group, we just do the insertion sort
      # where each element is G item apart
      pos = round-G
      ✓ while pos > 0
        tmp = A[pos]
        i = pos+G
        ✓ while (i <= n && tmp > A[i])
          A[i-G] = A[i]
          i = i + G
          A[i-G] = tmp
        pos = pos - 1
```

5 - 2 + 1

5 - 3 + 1

1 2 3 4 5  
0 1 2 3 4

นี่คือการเรียงแบบ

- Code can be shorter

```
for (int i = 1; i < gaps.size(); i++) {
  G = gaps[i];
  for (pos = n; pos >= n-G+1; pos -= G) {
    tmp = A[pos]
    i = pos + G
    while (i <= n)
      pos = pos - 1
  }
}
```

# Analysis

- Very hard
- We know that when  $G = 1$ , it is basically the insertion sort
  - So it is  $O(N^2)$  with  $\Theta(N)$  best case มีจุดนี้แหละ
  - $G = 1$  is required at the last step so we can guarantee that the array is sorted
- The performance actually depends on the sequence of  $G$ 
  - $G$  ี่ต้องให้ได้

# Analysis

$N = 100$
