

Divide & Conquer

Did you mean recursion?

What is?

- D&C is an algorithm **design framework**
 - Some problem can be efficiently solve by this design, some are not
- Key Idea:
 - Solve a problem instance by **divide** it into smaller instances of the same type
 - A smaller instances is called a subproblem
 - Use recursive to solve the subproblems
 - The subproblem is also solved in the same way: recursive
 - The subproblems are divided repeatedly until the instance can no longer be divide, which should be very small instance that can be solved directly
 - Conquer (Combine) the result of subproblem into a result of the original instance

Solve(A)
A₁
A₂
A₃
L Solve(A₁)
~ (A₂)
(A₃)

D&C and Recursive Programming

- Divide and Conquer **extensively** use recursion
- It is much easier to do recursion according to the definition of D&C
- Analysis of D&C usually be done by Master Method

$$T(n) : \overbrace{a T(n/b)}^{\text{Recurrence}} + O(n^d)$$

Example

- We will discuss several example
 - Binary Search
 - Merge Sort
 - Quicksort
 - Modulo exponential
 - Maximum Contiguous Sum of Subsequence
 - Strassen's Matrix Multiplication
 - Closest Pair

Binary Search

Handwritten notes and calculations for a game involving numbers 1 through 10. Some numbers are circled or highlighted in orange. Various mathematical operations and sequences are shown.

Top row from left to right:
 1. A sequence of numbers with circled 5: 1, 2, 4, 6, 7, 12, 15, 20.
 2. Handwritten zeros: 0 0 0
 3. Handwritten zeros: 0 0 0
 4. Handwritten 1 3 4

Middle row from left to right:
 1. A sequence of numbers with circled 5: 1, 2, 4, 6, 7, 12, 15, 20.
 2. Handwritten zeros: 0 0 0
 3. Handwritten zeros: 0 0 0
 4. Handwritten 1 2 3

Right side:
 1. Handwritten 1 2 3
 2. Handwritten 5 2
 3. Handwritten 6 7 8 9 10

Center:
 - Circled 2
 - Circled 5
 - Circled 4

Mathematical calculations:
 $2 \times 2 = 1 \quad 0 \quad 0 \quad 0 \quad 0 \quad 2 \quad 2 \quad 4 \quad 9 \quad 5 \quad 6 \quad 6$
 $4 + 0 = 4 \quad 4 + 5 = 9 \quad 6 + 8 = 14$
 $6 + 10 = 16$
 $2 \times 2 = 4 \quad 2 \times 5 = 10 \quad 2 \times 6 = 12 \quad 2 \times 10 = 20$
 $x/2 = 1 \quad x/2 = 2 \quad x/2 = 3$
 $x/5 = 1 \quad x/5 = 2 \quad x/5 = 3$
 $1 + 2 + 3 = 6$
 $\frac{1}{2} + \frac{1}{3} + \frac{1}{5} = \frac{1}{6}$
 $x \left(\frac{1}{2} + \frac{1}{3} + \frac{1}{5} \right) \times 5 = 12$

Bottom left:
 A grid of numbers:
 Row 1: 0 3
 Row 2: 0 2 2
 Row 3: 4 5 1
 Row 4: 5 6 2
 Row 5: 7 8 2
 Row 6: 9 10 11 10 3

Bottom right:
 A sequence of numbers:
 12 0 4 5 6 12 1 9 8 7 6 5 6 7 8 9 10 11 5

Bottom center:
 A box divided into three sections: 9, 2, 3. Below it is a circled 3.

Binary Search Problem

- Input:

- Array $A[1..n]$, sorted, $n \geq 1$ *ສອງຈາກນັດວຽກ*
- A key k *ເຄີຍຫຼຸດໃນກະລຸນາ*

- Output:

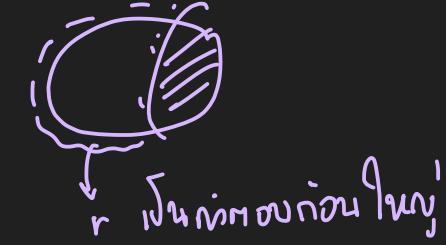

- If k exists in A , return its first position
- If k does not, return -1

- Example

- Input: $A = [1, 2, 4, 5, 6, 7, 8, 10]$, $k = 4$ output: 3 *ມີຄົນທີ່ມີຄົນ*
- Input: $A = [1, 2, 4, 5, 6, 6, 6, 10]$, $k = 6$ output: 5 (not 6 nor 7)
- Input: $A = [1, 2, 4, 5, 6, 6, 6, 10]$, $k = 100$ output: -1 *ບໍ່ມີ*

ԱՐԵՎԻ

A method to design D&C algorithm

- Consider a generic problem instance $\xrightarrow{n} \{n-k\}$ $\xrightarrow{n} \{n-1\}$
- Ask: if we know output of smaller instance, how can we use it to construct the output of the original instance
- Try:
 - Dividing problem into a subproblem with $n-1$ input, the idea might help solve larger division into $n-k$ inputs
 - Dividing problem into k non-overlapping subproblems, usually 2 problem of the same size

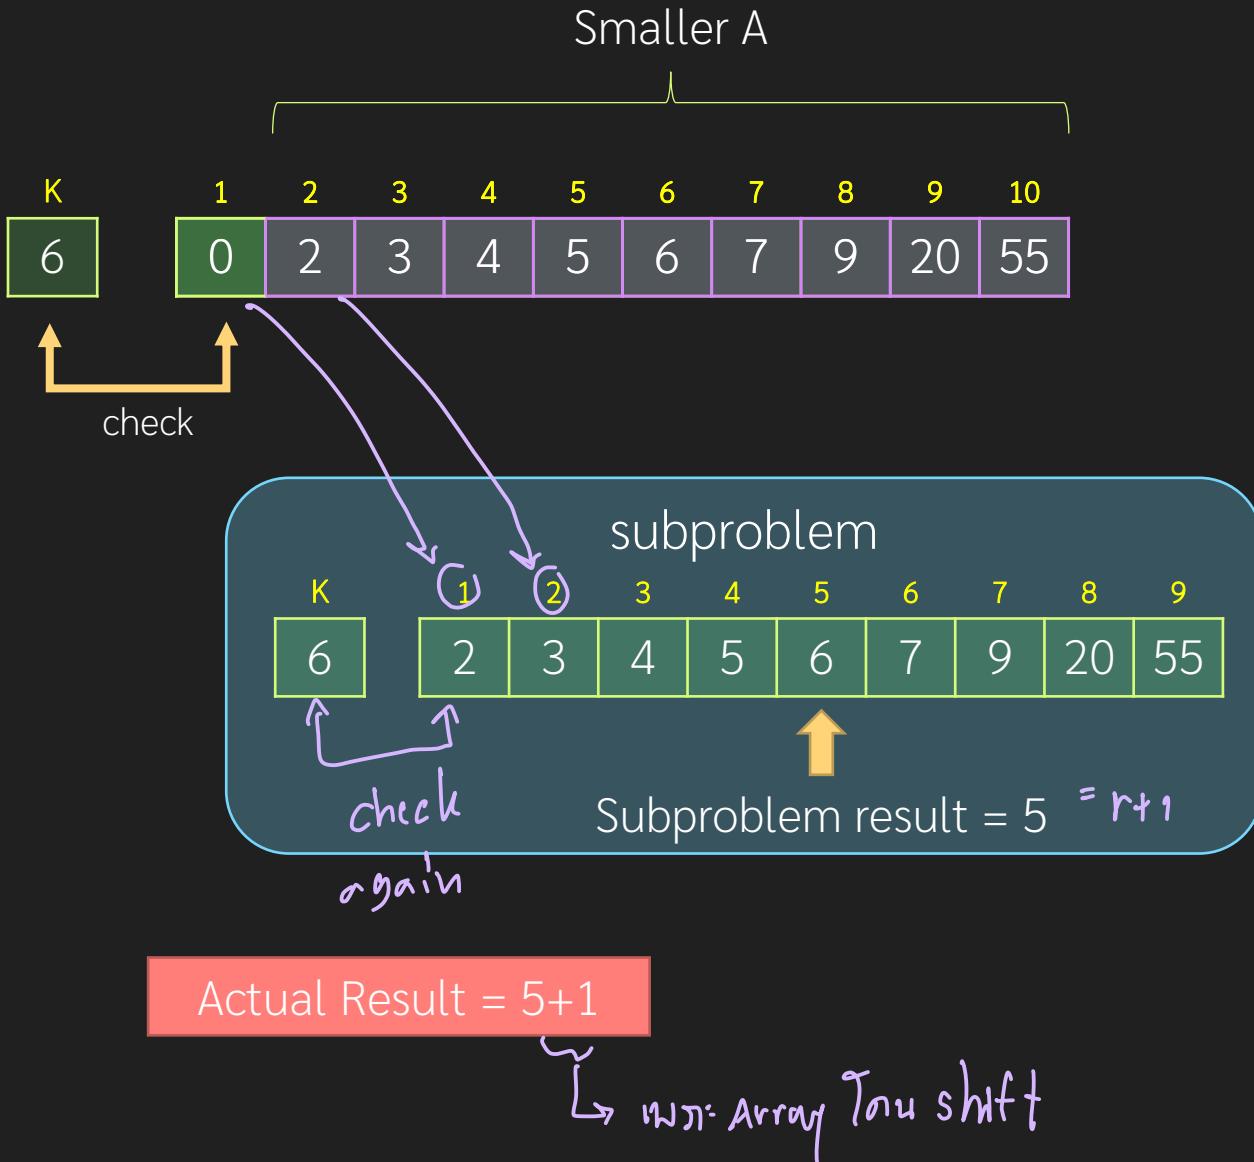

Binary Search, Naïve Approach

```
def bsearch_naive(A[1..n],k)
    for i from 1 to n
        if A[i] == k
            return i
    return -1
end
```

- Normal linear search
- $O(N)$
- Does not utilize the fact that
 $A[1..n]$ is sorted

Binary Search, D&C v 0.1

- Key Idea
 - A subproblem is exactly another instance of a Binary Search
 - Divide: $A[1..n], k$ into $A[2..n], k$
 - Conquer: if $A[1]$ is K , return 1, if not return the result of the sub problem
 - Need to adjust position
 - Trivial case: when $n == 1$, we check only $A[1]$ without doing any subproblem

Pseudo-code and its analysis

terminating cond.

```
def bsearch_slow(A[1..n],k) = T(n)
    if [n == 1]
        if A[1] == k
            return 1
        return -1
    if A[1] == k
        return 1
    else
        B = A[2..n]  $\rightarrow O(n)$ 
        r = bsearch_slow(B,k)  $\hookrightarrow T(n-1)$ 
        if r != -1
            return r+1
        else
            return r
end
```

recursive
case

$O(n)$

- Trivial case becomes initial condition of the recurrence relation $T(1) = O(1)$
- $T(N) = T(n-1) + a + b$
 - $a = \text{time to divide}$ the problem
 - $O(N)$ in this case (because we need to create another array)
 - $b = \text{time to conquer}$ the problem
 - $O(1)$
- $T(n) = T(n-1) + O(n)$

 $T(1) = 1$

Solving

$$T(n) = \begin{cases} T(n - 1) + O(n) & ; n > 1 \\ 1 & ; n = 1 \end{cases}$$

- By substitution

$$\begin{aligned} T(n) &= T(n - 1) + n \\ T(n - 1) &= T(n - 2) + n - 1 \\ T(n - 2) &= T(n - 3) + n - 2 \\ \dots \\ T(n - i) &= T(n - i - 1) + n - i \\ \dots \\ T(n - (n - 2)) &= T(n - (n - 1)) + 2 \\ T(1) &= 1 \end{aligned}$$

Sum both sides of the equation,
Recursive terms cancel out

$$\text{Result is } T(n) = \sum i = \frac{n(n+1)}{2} = \boxed{O(n^2)}$$

Verifying $O(n)$

This is slower than naïve!
Because our division is too slow

Improving v0.1

```

template <typename T>
int bsearch_slow(queue<T> &v, T k) {
    if (v.size() == 1) {
        if (v.front() == k)
            return 0;
        return -1;
    } else {
        if (v.front() == k)
            return 1;
        v.pop();  $\leftarrow O(1)$ 
        int r = bsearch_slow(v,k);
        return (r == -1) ? r : r+1;
    }
}

int bsearch_slow(vector<T> &v, T k) {
    queue<T> q;
    for (auto &x : v) q.push(x);  $\leftarrow O(n)$  រាយ vector  $\Rightarrow$  queue
    return bsearch_slow(q,k);
}

```

- Better subproblem division using queue

$$T(n) = T(n-1) + 1$$

- Solve into $T(N) = O(N)$

- We also need $O(N)$ (only one time) to convert a given array into a queue
 - Still result in $O(N)$ total time

- We can do better!

Much better v0.1

ັນກາສົງ ສ່ວນຕາມໄດ້ $0 \dots n-1$

```
template <typename T> [start... v.size()-1]
int bsearch_slow_2(vector<T> &v, T k, int start) {
    if (start == v.size() - 1) {
        if (v[start] == k) return start;
        return -1
    } else {
        if (v[start] == k) return start;
        return bsearch_slow_2(v, k, start+1);
    }
}
```

```
template <typename T>
int bsearch_slow_2(vector<T> &v, T k) {
    return bsearch_slow_2(v, k, 0);
}
```

ຖີ່ ຜົດນີ້!
↳ $\sigma = n-1$

```
template <typename T>
int bsearch_slow_3(vector<T> &v, T k, int start) {
    if (v[start] == k) return start;
    if (start == v.size()-1) return -1;
    return bsearch_slow_3(v, k, start+1);
}

template <typename T>
int bsearch_slow_3(vector<T> &v, T k) {
    return bsearch_slow_3(v, k, 0);
}
```

- We can DRY the code further
- Better code, but still $T(N) = O(N)$, not faster than naïve method

ໃຫ້ ຕິດຈິບກົດລົງຈຳກັດ

V0.1 Summary

$$T(n) = T(n-1) + O\left(T(n-1) + \dots + O\right)$$

- Use one smaller subproblem (less by 1) to help solve the original problem
- Need to divide 
- Need to conquer
- Using correct data structure (or better indexing) helps getting better performance
- Pseudo-code can tell the idea more clearly but implementation details depends on expertise in programming

V0.2: Different Division

- V0.1 divides n into n-1, and solve the remaining 1
- Can we try divide A of size n into 2 array of size $n/2$?

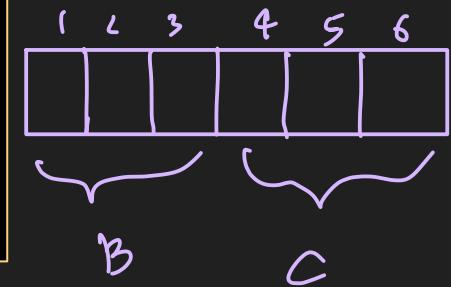

$$T(n) = \begin{cases} 2T(n/2) + O(1) & ; n > 1 \\ 1 & ; n = 1 \end{cases}$$

Assume that we use indexing technique to get B, C efficiently

Can we use Master Method to solve this into $O(N)$?

```
def bsearch_half(A[1..n], k)
    if n == 1
        if A[1] == k
            return 1
        return -1
    m = n/2
    B=A[1..m]
    r = bsearch_half(B, k);
    if r != -1
        return r
    C=A[m+1..n]
    r = bsearch_half(C, k);
    if r != -1
        return r + m
    return -1
end
```

សំពាល់ទីនេះ មានវាយដោយ

Divide into two subproblems of similar size

1	2	3	4	5	6	7	8	9	10
-1	-5	9	10	15	22	40	50	72	99

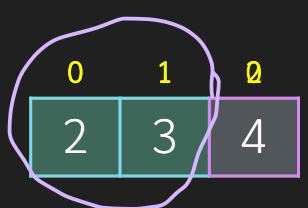

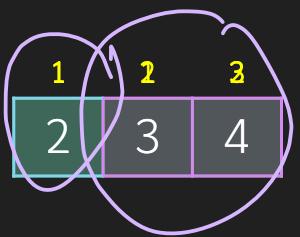

1	2	3	4	5
-1	-5	9	10	15

Subproblem 1

1	2	3	4	5
22	40	50	72	99

Subproblem 2

$$\begin{aligned}n &= 3 \\m &= 1\end{aligned}$$

- Divide by $m = n/2$
 - Integer division
- Subproblem 1 = 1.. m
- Subproblem 2 = $m+1..n$
- For odd number of n , starting index is relevant to the size of each subproblem

Recap

- Naïve (non-)Binary Search is a linear search using $O(N)$
- V0.1 is just a linear search written as a divide and conquer
 - The cost of divide has to be managed so that the recurrence relation is $T(n) = T(n-1) + 1 = O(n)$
- V0.2 tries to divide into 2 equal subproblems
 - $T(n) = 2T(n/2) + 1 = O(n)$, different recurrence relation but same performance
- To get better performance, we need to reduce the number of subproblems

Actual Binary Search

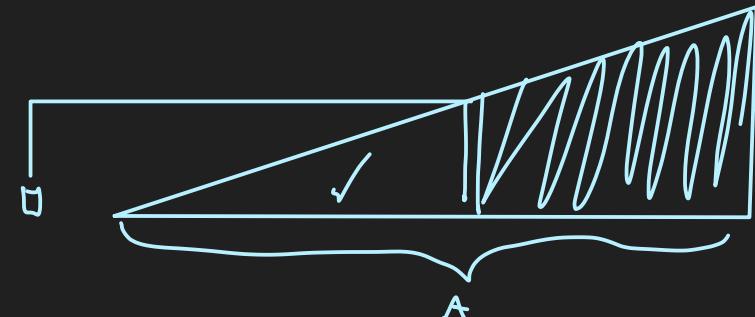

- Utilize the fact that the  **data is sorted**
- We will divide the problem into 2 parts: **left** and **right**
 - Check the **middle point**
 - only one part is solved, the other is discarded, depends on the value of the middle point

$$T(n) = \begin{cases} T(n/2) + O(1) & ; n > 1 \\ 1 & ; n = 1 \end{cases}$$

The result is $T(n) = O(\log n)$

```
def bsearch(A[1..n],k)
    if n == 1
        if A[1] == k
            return 1
        return -1
    else
        m = n/2
        if A[m] == k
            return m
        r = bsearch(A[1..m],k)
        else
            if A[m] < k
                r = bsearch(A[m+1..n],k)
            if r != -1
                r = r + m
    return r;
end
```

ເພື່ອນໄດ້ກຳນົດກີ່າວ່າມີປົວກັນ
 $T(n/2)$ $S(n/2)$

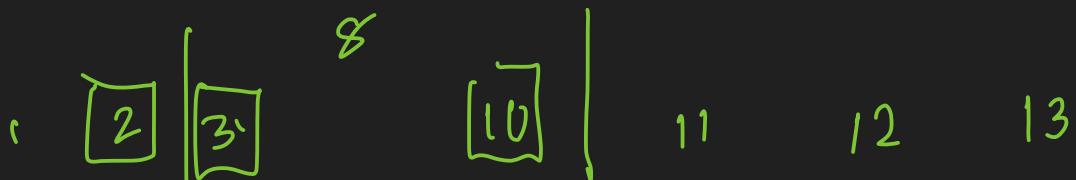

Actual Code

பொது
நடவடிக்கை

```
template <typename T> int bsearch(vector<T> &v, T k, int start, int stop) {  
    if (start == stop) return v[start] == k ? start : -1;  
    int m = (start+stop) >> 1; //bitwise shift right  
    if (v[m] >= k) return bsearch(v,k,start,m);  
    else return bsearch(v,k,m+1,stop);  
}
```

```
template <typename T>  
int bsearch(vector<T> &v, T k) {  
    return bsearch(v,k,0,v.size()-1);  
}
```

- Using moving index
 - Non-recursive
- முறையூற்று 2 version exists

$$\sigma \sim n - 1$$

What's wrong with these code?

(a)

```
template <typename T>
int bsearch(vector<T> &v, T k, int start, int stop) {
    if (start == stop) return v[start] == k ? start : -1;
    int m = (start+stop) >> 1; //bitwise shift right
    if (v[m] == k) return m; ←
    if (v[m] <= k) return bsearch(v,k,m+1,stop); ↗
    if (v[m] > k) return bsearch(v,k,start,m-1);
}
```

- Does it work correctly according to the problem definition?

(b)

```
template <typename T>
int bsearch(vector<T> &v, T k, int start, int stop) {
    if (start > stop) return -1;
    int m = (start+stop) >> 1; //bitwise shift right
    if (v[m] >= k) return bsearch(v,k,start,m);
    else return bsearch(v,k,m+1,stop);
}
```

↗: return $v[m] \geq k$?

1 2 3 4 5 6 7 8
↙ $\{ 4 \leq 6 \}$

```
template <typename T>
int bsearch(vector<T> &v, T k) {
    return bsearch(v,k,0,v.size()-1);
}
```

Non recursive version

- It is possible to write Binary Search as a loop
 - Maintain two variable, `start` and `stop`
 - Each iteration, `start` and `stop` move closer to each other
- When should be `stop`?
 - What happen when `start = stop` ?
 - Also when `start+1 = stop`?
- Try it yourself

નુંબળ પત્ર

$$T(n) = T\left(\frac{n}{2}\right)$$

(સમયજીવન)

Summary for Binary Search

- First example of divide and conquer
- Different dividing strategies may give different performance
 - Not necessarily better than naïve method
- Pseudo-code is better in providing idea and insight
- Actual code is better in analysis
- Care should be taken when converting pseudo-code into a code
- D&C Benefit can be achieved when we divide by half

សំបាលមុនការវិភាគ

Merge sort

D&C Sorting, easy divide

The Sorting Problem

- Input:
 - Array $A[1..n]$ of n data (we must be able to compare a pair of them)
- Output:
 - The same array but re-arranged such that $A[i] \leq A[i+1]$ for every i from 1 to $n-1$ ຕ້ອງຮັດ ດີນ ເປົ້າຍືນດໍາໄວ້ໄດ້
- Example instance
 - Input: [1,5,3,2,7,1]
 - Output: [1,1,2,3,5,7]

Sorting by Divide & Conquer

- We have iterative sorting that is $O(n^2)$ such as insertion sort or selection sort
- If, for D&C we get $T(n) = T(n-1) + O(n) \rightarrow O(n^2)$ 
- To go better than that, we need
 - $T(n) = T(n-1) + O(\log n) \rightarrow O(n \log n)$
 - $T(n) = 2T(n/2) + O(n) \quad n \log n$
- Either reduce by one and conquer in $O(\log n)$
 - Can we re-write our heapsort into a divide & conquer with $T(n) = T(n-1) + O(\log n)$
- For Merge sort, it is $T(n) = 2T(n/2) + O(n)$

Merge Sort

- Invented by John von Neumann in 1945

- Divide:

- At middle point, into 2 non-overlapping subproblems

- Conquer:

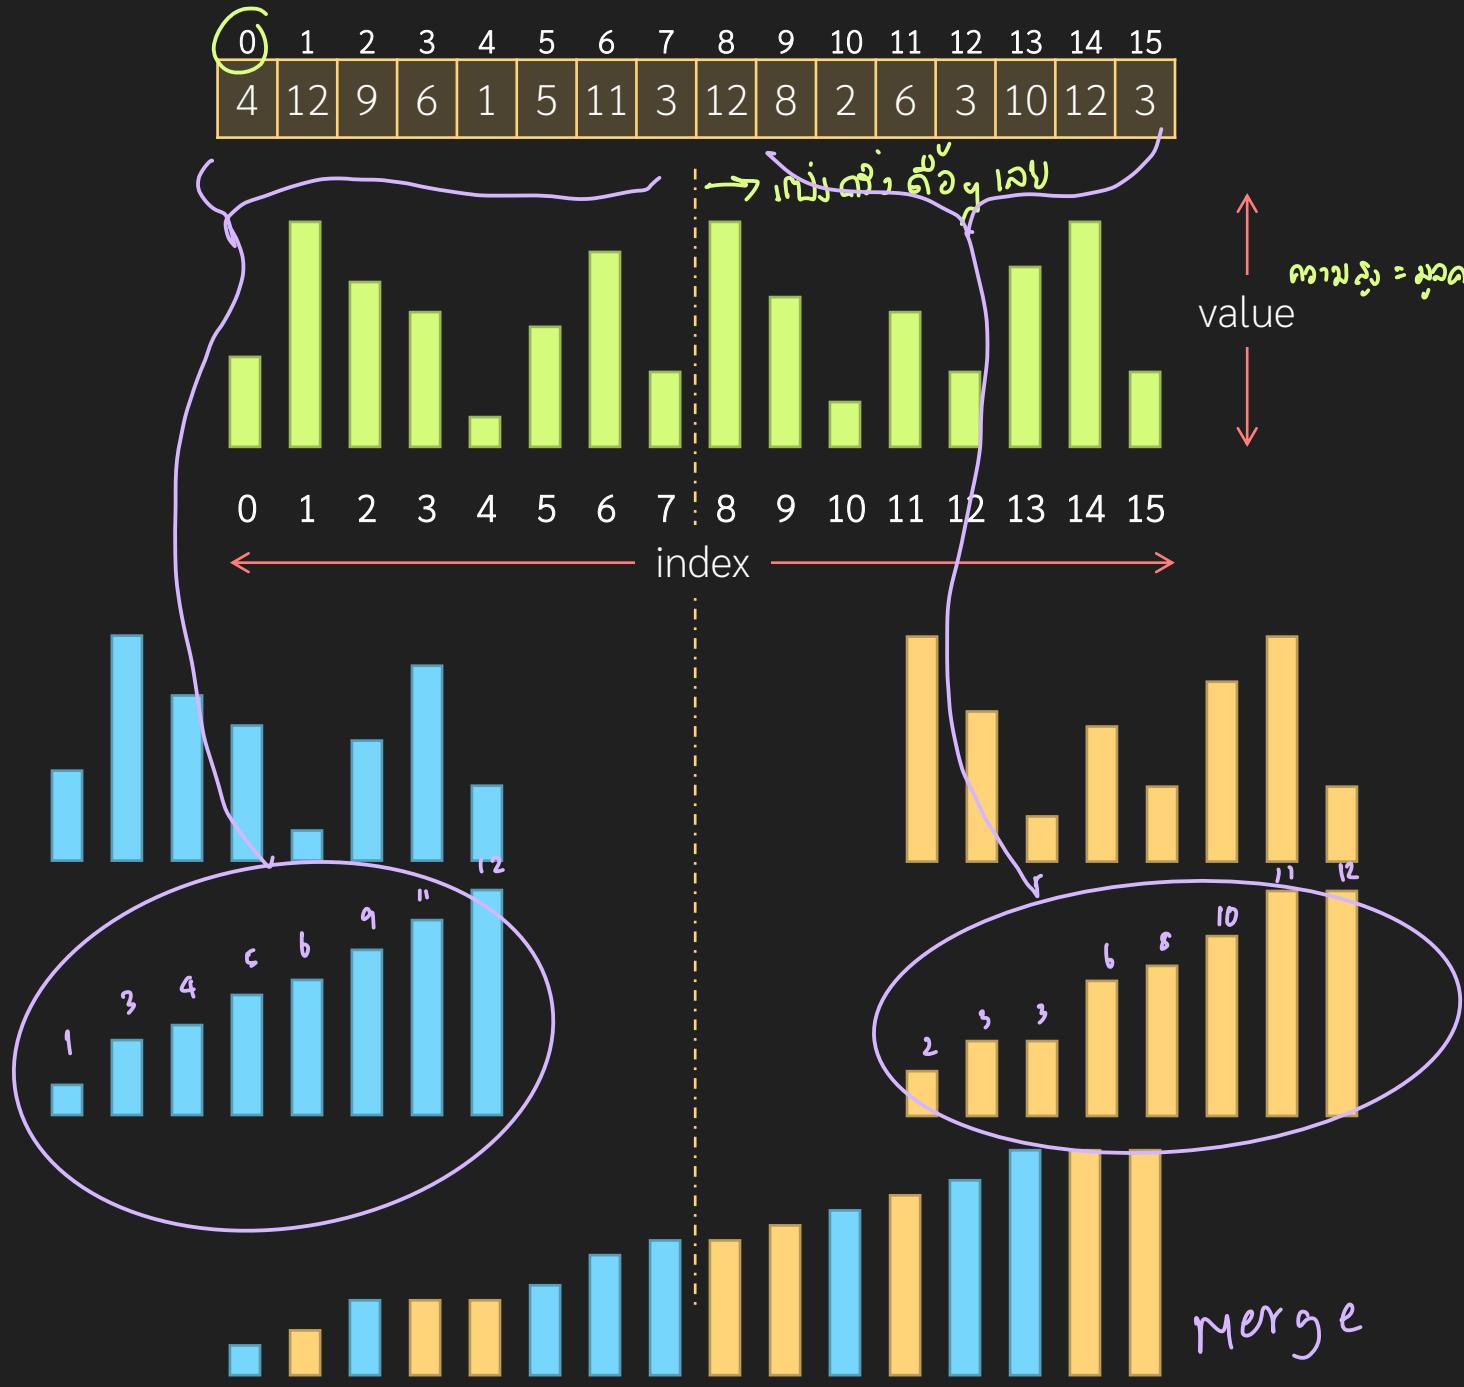

- Merge 2 sorted array into one

$$T(n) = 2T\left(\frac{n}{2}\right) + O(n)$$

Study under
David Hilbert

Example

- Divide at middle point
- Solve each part recursively
- Merge two sorted array

Pseudocode

- How to merge?
- Think of selection sort, we pick the maximum of the unsorted and move to front of sorted
 - For merge, our unsorted is actually two parts, each is already sorted
 - Picking maximum of the two sorted array is very simple, just compare the max of each array
 - Can also start from minimum

ນີ້ແມ່ນການຈົບຂອງລົງທະບຽນ

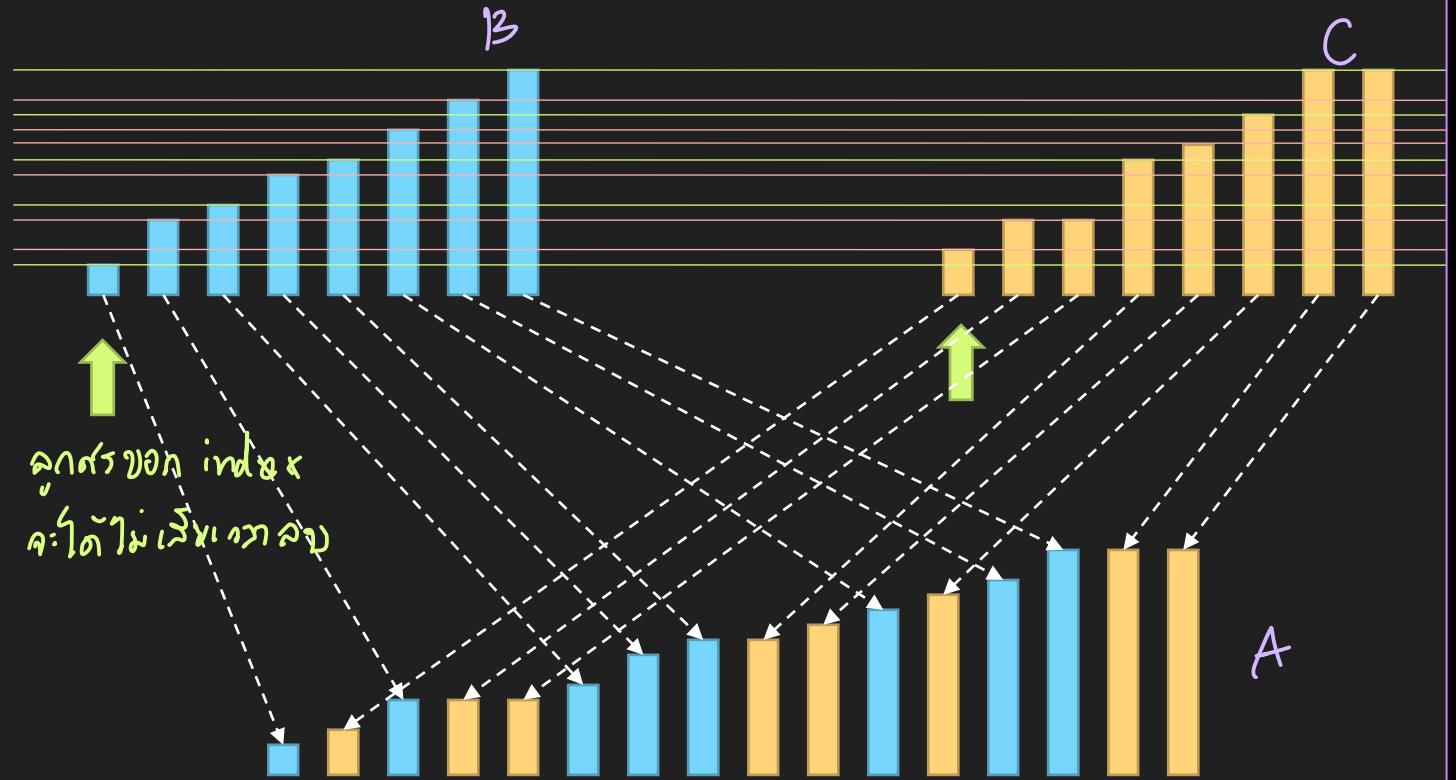

```
def merge_sort(A[1..n])
    if n == 1
        return A
    m = n/2
    B = merge_sort(A[1..m])
    C = merge_sort(A[m+1..n])
    A = merge(B,C)
end
```

$O(n)$

$$T(n) = \begin{cases} 2T(n/2) + T_{\text{merge}} & ; n > 1 \\ 1 & ; n = 1 \end{cases}$$

The result is $T(n) = O(n \log n)$ //
if T_{merge} is $O(n)$

Merge

```
#B and C is sorted
array B is O(n)
array C is O(n)

def merge(B[1..m],C[1..n])
    A = []
    while (B is not empty || C is not empty)
        if (B is not empty && C is not empty)
            if B[1] < C[1]
                move front of B to the end of A
            else
                move front of C to the end of A
        else
            if (C is empty)
                move front of B to the end of A
            else
                move front of C to the end of A
    end
    return A
end
```

ขนาด 2^{k-1} ที่นำมาต่อ กันเป็นไวรัสขนาด 2^k การต่อ กันได้นั้นจะมีกฎสำคัญคือ จำนวนต่างจากจำนวน 1 ใน b เกิน 1 ตัว

เราต้องการตรวจสอบหัสพันธุกรรมหลาย ๆ รหัส ที่ได้รับมาว่า ตรงกับไวรัส DOVIC

ข้อมูลนำเข้า

- บรรทัดแรกประกอบด้วยจำนวนเต็ม 2^k ตัวคือ n และ k โดยที่ n ระบุจำนวนรหัสพันธุ์ บอกขนาดของรหัสพันธุกรรม โดยที่ $2 \leq n \leq 10$ และ $1 \leq k \leq 8$
- หลังจากนั้นอีก n บรรทัดจะเป็นรหัสพันธุกรรม บรรทัดละ 1 รหัส
 - แต่ละบรรทัดจะประกอบด้วยจำนวนเต็ม 2^k ตัว แต่ละตัวเป็นเลข 0 หรือ 1

ข้อมูลส่งออก

มี k บรรทัด เพื่อระบุว่ารหัสพันธุกรรมแต่ละรหัสเป็นไวรัส DOVIC-20 หรือเปล่า ให้พิ และ “go” ถ้าไม่เป็น (ตัวพิมพ์เล็ก)

ตัวอย่าง

ข้อมูลนำเข้า	ข้อมูลส่งออก
5 2	yes
0 0 0 0	no
0 0 1 1	yes
0 1 1 1	yes
1 0 0 0	yes
0 1 0 1	yes
4 3	no
0 0 1 1 0 0 1 1	no
1 / 2 - 3	no
0 0 1 1 1 0 0 0	yes
0 1 0 1 0 1 1 1	no
0 1 0 1 1 1 0 0	no
3 4	no
1 1 1 1 1 1 1 0 0 1 1 1 1 1 0 0	yes
1 1 1 1 1 1 1 0 0 1 1 1 1 1 0 1	yes
1 1 1 0 0 1 1 1 1 0 0 1 1 0 1 1	

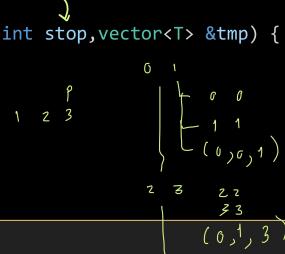

ชุดข้อมูลทดสอบ

- (30%) $k \leq 4$

More on Merge Sort

$O(n \log n)$

- Comparing to **heap sort**, merge sort requires more temporary space

- Both is $O(n \log n)$

↳ តាមរាងការ ពីលេខក្នុងវិវាទ

python - pin sort
(merge sort, insertion sort)
↓
sinh vui n lèn,
n ឱ្យ

- Merge sort is better for **sorting linked list** where random access is slow

- Because it consider adjacent element
- Used in external sorting and parallel sorting

- Sort in python is **Timsort** which is a hybrid of **Insertion sort** and **merge sort**

- when sort small amount of data, use insertion, for larger, use merge

Question

- Instead of divide by half, can we divide into 4 sub problem of same size?
 - $T(N) = 4T(n/4) + O(n)$
 - How to merge?
 - Better performance? $n \lg n$
- Can we divide into $n/2$ subproblem?
 - What is the complexity?

Quick Sort

D&C Sorting, easy merge

Quicksort \rightarrow ខាងក្រោម តម្លៃ ស្ថិត នូវ + ឯករាជការ merge sort

- Invented in 1959 by Sir Charles Antony Richard Hoare
- Merge sort need large temporary space, can we do better?
 - Instead of merge, can we use simplest possible conquer
- Quicksort achieve this by require additional condition for subproblem
 - We have to divide the problem smartly so that the subproblem satisfy this condition

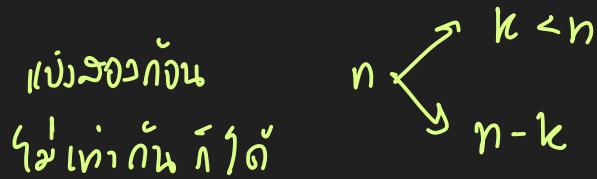

Study under
Andrey Kolmogorov

ពាក្យទាំង ១២៧ គុណភាព ឱ្យបាន

អំឡុង ចាប់ពី

Quick Sort D&C

- Divide:

- two subproblems, maybe different size

- Additional condition

- Pick a pivot (ຕົວທີ)

- Subproblem 1 must contains only $A[i]$ such that $A[i] \leq \text{pivot}$

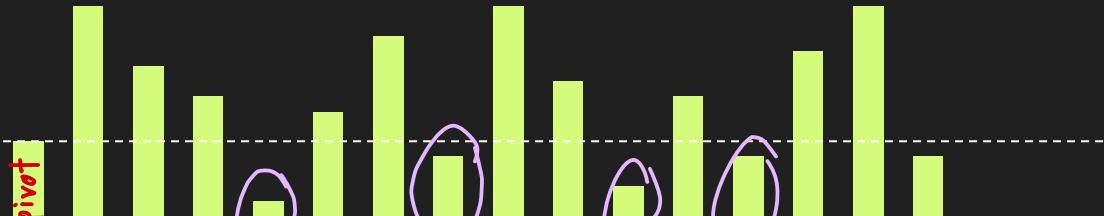

- Subproblem 2 must contains only $A[i]$ such that $A[i] > \text{pivot}$

ເວັບໄວ $>=$

- Conquer:

- Because every data in the sub1 is less than elements of sub2, we can conquer by just append sub2 to sub1

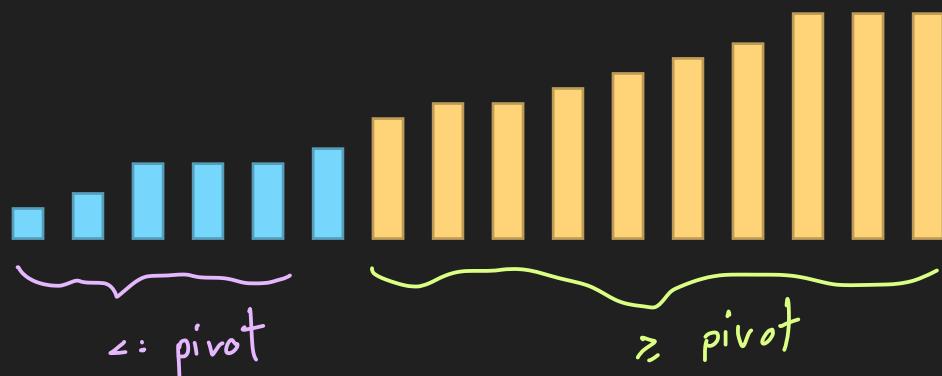

Example

$\leq \text{pivot}$

- Pick a partition
- Divide into \leq partition part and \geq partition part
- Sort recursively
- Just attach result together

Subproblem 1 Subproblem 2

$\leq \text{pivot}$

$\geq \text{pivot}$

Pseudocode

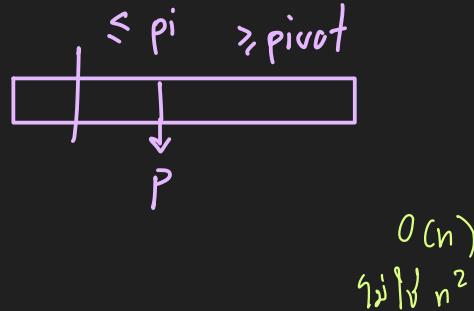

ແກບໃຈຕັ້ງກິດ Merge

```
def quick_sort(A[1..n], start, stop)
    if start < stop
        p = partition(A, start, stop) →
        quick_sort(A, start, p)
        quick_sort(A, p+1, stop)
    end
```

↓ ໃຫ້

- Partition by Hoare's algorithm →
- There is a simpler partitioning algorithm by Nico Lomuto ← ຂັ້ນ ຂົນໄດ້ງ່າງກວ່າ ນັງປັດຈຸບັນກ່າວໜີເມນີຍ
- Both is $O(n)$

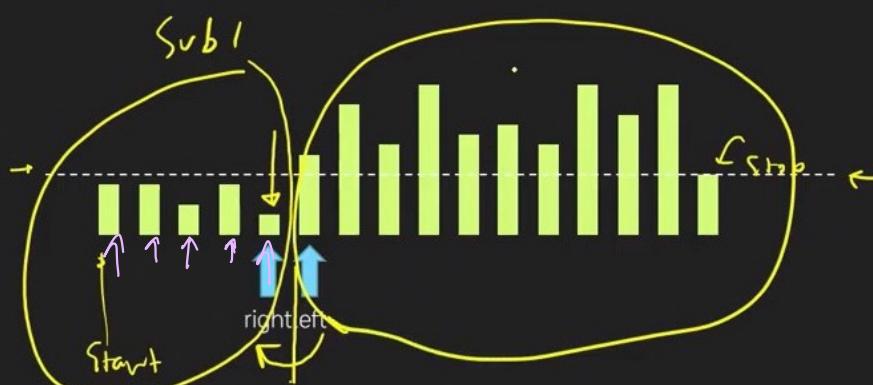

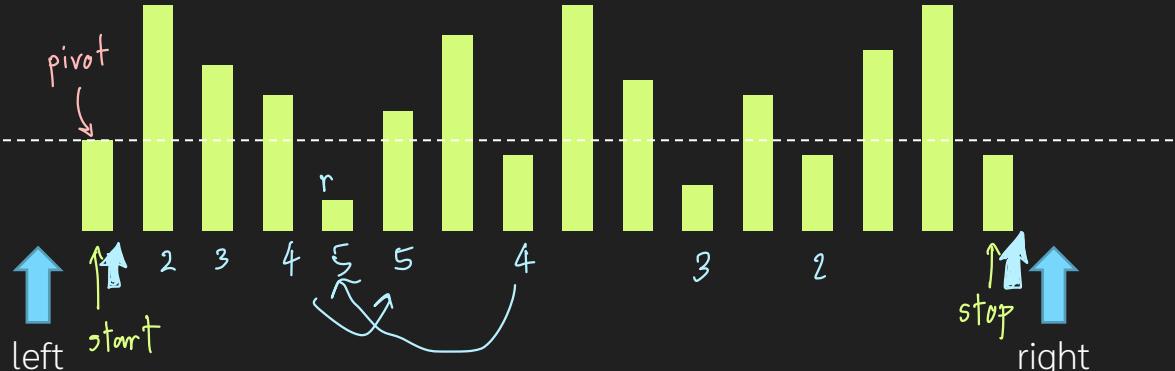

q sort(A)
↳ quick-sort(A, 1, A.size)

```
def partition(A[1..n], start, stop)
    #can use anything except stop
    pivot = A[start]; ເສັກຕົວແທກ
    → left = start-1 } ນອກຈອງ
    → right = stop+1 } ນອກຈອງ
    while (left < right)
        do ມີຂອງຕົວວ່າ check condition ຫຼັດ loop
            left = left + 1 ລວມ >= ຖະແນກ
        until (A[left] >= pivot)
        do
            right = right - 1
            until (A[right] <= pivot)
            if (left < right) ອັນກົນຍືນ
                swap(A[left], A[right])
            else
                return right
            end
            return right
        end
```

The pseudocode for the partition function is shown within a large brace, indicating its scope. The code uses Hoare's algorithm for partitioning. It initializes `left` to `start-1` and `right` to `stop+1`. It then enters a `while` loop where it moves `left` to the right until `A[left] >= pivot`. It also moves `right` to the left until `A[right] <= pivot`. If `left < right`, it swaps the elements at `A[left]` and `A[right]`. Finally, it returns the value of `right`.

Partitioning

```
def partition(A[1..n], start, stop)
    #can use anything except stop
    pivot = A[start];

    left = start-1
    right = stop+1
    while (left < right)
        do
            left = left + 1
            until (A[left] >= pivot)
        do
            right = right - 1
            until (A[right] <= pivot)
            if (left < right) O(n)
                swap(A[left], A[right])
            else
                return right
        end
    return right
end
```

Analysis

$$T(n) = T(k) + T(n-k) + O(n)$$

- We cannot directly use Master Method
 - Because we don't know that the subproblems actually equally divide
- Consider worst case and best case
 - Worst case, each partition result in very imbalance subproblem
- Best case, each partition is balanced

$$\begin{aligned} \bullet \quad T(n) &= \underbrace{T(1)}_{O(n^2)} + \underbrace{T(n-1)}_{\text{worst case}} + O(n) & T(n) &= T(n-1) + n + 1 \\ \bullet \quad \text{This is } O(n^2) & & T(n-1) &= T(n-2) + n \dots \end{aligned}$$

$$\bullet \quad T(n) = 2T(n/2) + O(n) \quad T(n) = T\left(\frac{n}{2}\right) + T\left(\frac{n}{2}\right) + O(n)$$

$$\bullet \quad \text{This is } O(n \log n)$$

底が n log n

Average Case

Let $f(n) = T_{avg}(n)$

⇒ ດີກິຈົບສະໜາມ

$$T(n) = T(k) + T(n - k) + n$$

$$T_{avg}(n) = \frac{1}{n} \sum_{i=1}^{n-1} (T_{avg}(i) + T_{avg}(n - i)) + n$$

ເປັນທົ່ວໄວ້ (ປິວຕົວ ໄລຍະຫຼວງທຳນານ)

$$= \frac{2}{n} \sum_{i=1}^{n-1} T_{avg}(i) + n$$

① ×

$$nf(n) = 2(f(1) + f(2) + \dots + f(n-2) + f(n-1)) + n^2$$

ແມ່ນ $n-1$ $(n-1)f(n-1) = 2(f(1) + f(2) + \dots + f(n-2))$

$$nf(n) - (n-1)f(n-1) = 2f(n-1) + n^2 - (n-1)^2$$

②

$$nf(n) = (n+1)f(n-1) + 2n - 1$$

(1)

(2)

(1)-(2)

$$\frac{nf(n)}{n(n+1)} = \frac{(n+1)f(n-1)}{n(n+1)} + \frac{2n-1}{n(n+1)}$$

$$\frac{f(n)}{(n+1)} = \frac{f(n-1)}{n} + \frac{2n-1}{n(n+1)}$$

Average Case

$$\frac{f(n)}{(n+1)} = \frac{f(n-1)}{n} + \frac{2n-1}{n(n+1)}$$
$$\frac{f(n-1)}{(n)} = \frac{f(n-2)}{n-1} + \frac{2(n-1)-1}{(n-1)((n-1)+1)}$$
$$\dots = \dots$$
$$\frac{f(2)}{3} = \frac{f(1)}{2} + \frac{2(2-1)}{2(2+1)}$$

$$\frac{f(n)}{(n+1)} = \ln(n) + c$$
$$f(n) = n \ln(n) + n^c + c$$
$$= \underline{\theta(n \log n)}$$

Partial sum harmonic series less than $\ln(k) + 1$

$$\frac{f(n)}{(n+1)} = \sum_{i=2}^n \frac{2i-1}{i(i+1)}$$
$$= 2 \sum_{i=2}^n \frac{i}{i(i+1)} - \sum_{i=2}^n \frac{1}{i(i+1)}$$
$$= 2 \sum_{i=2}^n \frac{1}{(i+1)} - \sum_{i=2}^n \frac{1}{i(i+1)}$$

something less than 0.5 ✓
because $\sum_{i=2}^{\infty} \frac{1}{i(i+1)} = 1 \approx \frac{1}{2}$
 $x \approx 0.5$

Quicksort's average case is $\theta(n \log n)$

How likely is the worst case ເຕີບື້ນນໍ່ຍິນ?

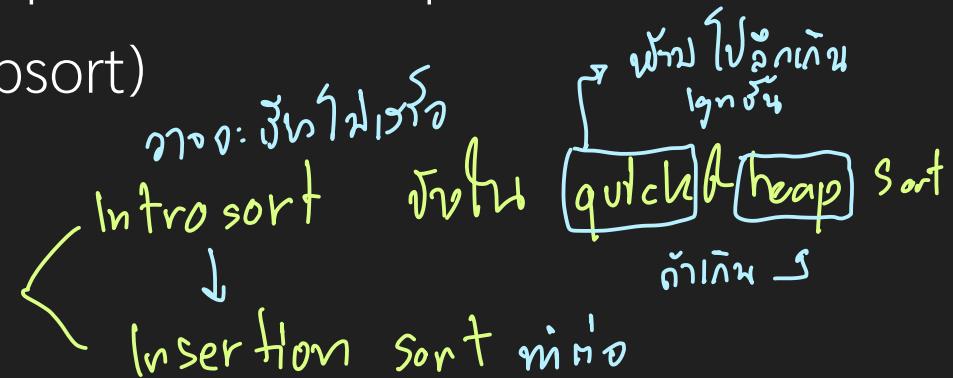

ເຕີບື້ນນໍ່ຍິນ ທັງລົມມາກ ດ້ວຍລູກໄສໂລງວ່າແລ້ວ ແລ້ວເວົາ pivot ສົນຕົກເກມ

- If we pick pivot by the first element (or the last element) and the data is sorted (either ascending or descending), it's worst case
- Can be practically avoided by picking pivot at random ແກ້
 - With Hoare's algorithm, do not pick a pivot at the last element
↳ ອຳເຫດຕ່າທົ່ວ

Dealing with quicksort uncertainty

insertion sort
introsort

- Sort of Gnu C++ use hybrid sort (similar to Timsort in Python)
 - Hybrid of Introsort follow by Insertion Sort
 - Introsort is a hybrid of Quicksort + Heapsort (when depth of recursion exceed some limit, we convert to heapsort)
- Better pivot selection
 - Median-of-median-of-five

ຈຸດຈັດ ນິກ
pivot $T(n) = T(0.3n) + T(0.7n) + O(n)$

Modulo Exponentiation

Calculating $a^n \bmod k$

Problem

- Calculate $a^n \bmod k$
- Input:
 - Three positive integers a , n and k
- Output:
 - The value of $a^n \bmod k$
- Example instance
 - $a = 2, n = 92, k = 10$ output: 4

Usage

$$t \xrightarrow{2^8} \boxed{\text{encription}} \xrightarrow{43275} \boxed{\text{decript}} \xrightarrow{2^8} t$$

នូវការការពារ
រាយការណ៍
ស្ថិតិយាល័យ
នក់បាន

នីមួយៗ
ដ

- m is calculated from $p * q$ where p and q are large prime number
- e is any integer from 1 to $\text{LCM}(p-1, q-1)$
- d is a modular inverse of e in mod $\text{LCM}(p-1, q-1)$

- Very easy to calculate d if we know e, p, q
- Very hard to calculate d if we know only e and m (but not p, q)

- Encrypt a value t as $c = t^e \text{ mod } m$
- Decrypt a value c by $t = c^d \text{ mod } m$

RSA នឹង $f(x)$ នៅក្នុង
ក្រុង d ដែលនឹងធ្វើឡើង
នៅក្នុងក្រុង

Divide & Conquer $a^n \bmod k$

- Observe that $(a \cdot b) \bmod k = [(a \bmod k) \cdot (b \bmod k)] \bmod k$

- Lets $n = x + y$ $400 = 100 + 300$ $a^{400} = a^{(100+300)} \bmod k = a^{100} \bmod k \cdot a^{300} \bmod k$

- Then, $a^n \bmod k = a^{(x+y)} \bmod k = (a^x \bmod k) \cdot (a^y \bmod k) \bmod k$

- In other words, to calculate $a^n \bmod k$, we need to calculate

- $a^x \bmod k$ and

- $a^y \bmod k$

- Now, let $x = n/2$

$$a^{400} = a^{200} \cdot a^{200}$$
$$a^{57} = a^{28} \cdot a^{28} \cdot a^1$$

$$\begin{aligned} a^{57} &\bmod k \\ \downarrow (a^{28} \bmod k)^2 \bmod k \\ \end{aligned}$$

$$a^n = \begin{cases} a^x * a^x, & x \text{ is even} \\ a^x * a^x * a, & x \text{ is odd} \end{cases} \cdot a \bmod k$$

Pseudocode

```
def mod_expo(a,n,k)
    if n == 1
        return a mod k
    if n mod 2 == 0 2171: ဂုဏ်ပြန်
        tmp = mod_expo(a,n/2,k) ပုဂ္ဂန်း
        return (tmp * tmp) mod k
    else
        tmp = mod_expo(a,n/2,k)
        tmp = (tmp * tmp) mod k
        return (tmp * [(a mod k)]) mod k
    end
end
```

- $T(n) = T(n/2) + O(1)$
- $T(n) = \underline{O(\log n)}$

Example $2^{92} \bmod 10$

$$2^{92} = 4951760157141521099596496896$$

$$2^{92} = 2^{46} \times 2^{46} = 4 \times 4 \bmod 10 = 6$$

$$2^{46} = 2^{23} \times 2^{23} = 8 \times 8 \bmod 10 = 4$$

$$2^{23} = 2^{11} \times 2^{11} \times 2 = 8 \times 8 \times 2 \bmod 10 = 8$$

$$2^{11} = 2^5 \times 2^5 \times 2 = \boxed{2 \times 2 \times 2} \bmod 10 = 8$$

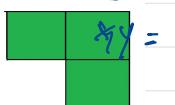

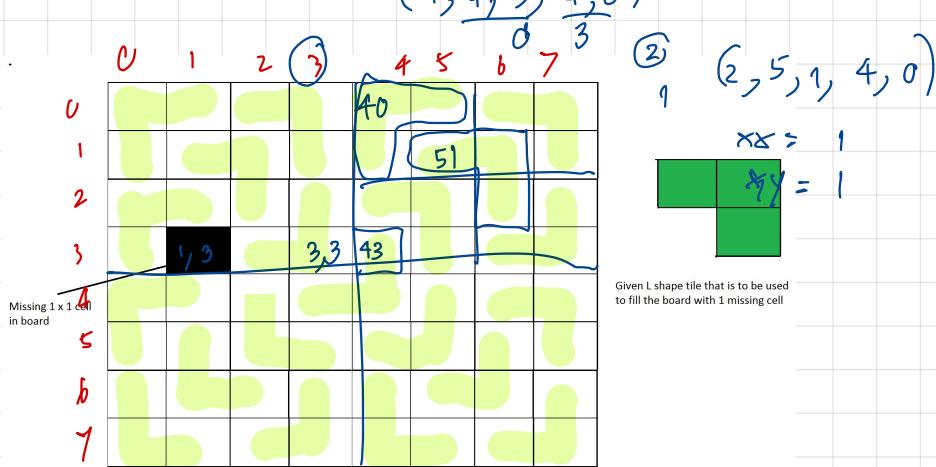

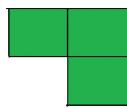

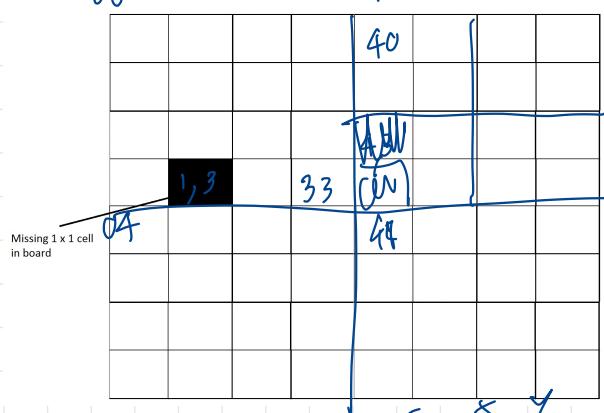

$$2^5 = 2^2 \times 2^2 \times 2 = \boxed{4 \times 4 \times 2} \bmod 10 = 2$$

$$2^2 = \boxed{2^1} \times \boxed{2^1} = 2 \times 2 \bmod 10 = 4$$

Maximum Sum of Subarray

The problem

- Given array $A[1..n]$ of numbers, may contain negative number
 - Find a non-empty subarray $A[p..q]$ such that the summation of the values in the subarray is maximum
↳ ຜົນທີ່ອຸປະກອນ ກັນທີ່ມວນວມມືດ້າມກວດຫຼຸງ
- Input:
 - $A[1..n]$ → ໃຊ້ array ໃນ 1 ດັວນ ຕຄນະໄສ
- Output:
 - p and q , where $1 \leq p \leq q \leq n$ and summation of $A[p..q]$ is maximum
- Example:
 - $A = [1, 4, 2, 3]$ output: 1 and 4
 - $A = [-2, -1, -3, -5]$ output: 2 and 2
 - $A = [2, 3, -6, 4, -2, 3, -5, -4, 3]$ output: 4 and 6

→ If divide & q mod

Naïve $O(n^3)$

↑ Σ array A

```
def mss_naive(A[1..n])
    max = A[1]
    for p from 1 to n
        for q from p to n
            sum = 0  $O(n^2)$ 
            for j from p to q
                sum += A[j]
            if (sum > max)
                max = sum
    return max
end
```

- Try all possible $O(n^2)$ subarray
- Need $O(n)$ per subarray to calculate the summation

$\Rightarrow O(n^3)$

Using prefix sum to reduce innermost loop

↳ $O(n^2)$

```
def mss_prefix_sum(A[1..n])
    let S be an array [0..n]
    S[0] = 0;
    sum = 0;
    for i from 1 to n
        sum = sum + A[i]
        S[i] = sum

    max = A[1]
    for p from 1 to n
        for q from p to n
            sum = S[q] - S[p-1]
            if (sum > max)
                max = sum
    return max
end
```

- Let $s[k] = \sum_{i=1}^k A[i]$

- Also $S[0] = 0$ $s[1] = A[1]$ $s[2] = A[1] + A[2]$

- Calculating $\sum_{i=p}^q A[i]$ is just $S[q] - S[p-1]$

A	1	2	3	4	5	6	7	8
	3	-4	1	2	-1	-1	5	-4

$$a_1 + a_2 + \dots + a_q - a_1 - a_2 - \dots - a_{p-1}$$
$$\underbrace{a_p - a_q}_{S[q] - S[p-1]}$$

$$1+2+-1-1+5 = 6$$

$S[0]$	1	2	3	4	5	6	7	8
	3	-1	0	2	1	0	5	1

$$5 - -1 = 6$$

D&C

- Try divide at the middle point
- Divide:
 - $m = n/2$
 - $A[1..n]$ into $A[1..m]$ and $A[m+1..n]$
- Conquer:
 - The answer from $A[1..m]$ is p_1, q_1 in range $[1..m]$
 - The answer from $A[m+1..n]$ is p_2, q_2 in range $[m+1..n]$
 - But we need to consider p in range $[1..m]$ while q is in range $[m+1..n]$

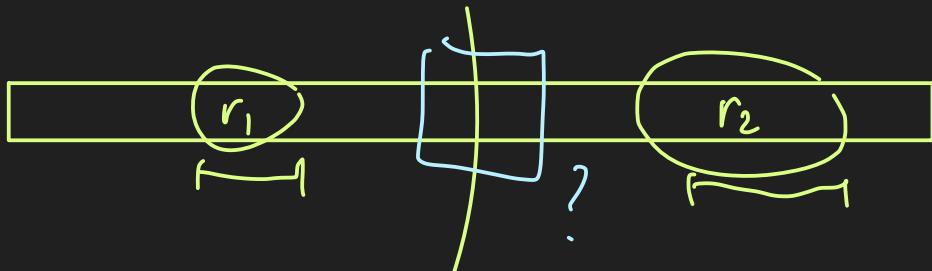

D&C v0.1

```

def mss1(A[1..n],start,stop,S)
    if (start == stop)
        return A[start]
    m = (start+stop) / 2
    r1 = mss1(A,start,m)
    r2 = mss1(A,m+1,stop)
    r3 = A[start]  $\text{M10}$ 
    for p from 1 to m  $\frac{n}{2}$ 
        for q from m+1 to n  $\frac{n}{2}$ 
            sum = S[q] - S[p-1]
            if (sum > r3)  $\rightarrow \left(\frac{n}{2}\right)^2$ 
                r3 = sum
    return max(r1,r2,r3)
end

```

$$\begin{aligned}
 T(n) &= 2T\left(\frac{n}{2}\right) + O(n^2) \\
 &= O(n^2)
 \end{aligned}$$

- Notice that $\sum_1^n A[i] = \sum_1^{n-1} A[i] + A[n]$
- Hence, $S[i] = S[i-1] + A[i]$

```

def mss1(A[1..n])
    let S be an array [0..n]
    S[0] = 0;
    for i from 1 to n
        S[i] = S[i-1] + A[i]
    mss1(A,1,n,S)
end

```

Visualization

1	2	3	4	5	6	7	8
3	-4	1	2	-1	-1	5	-4

```

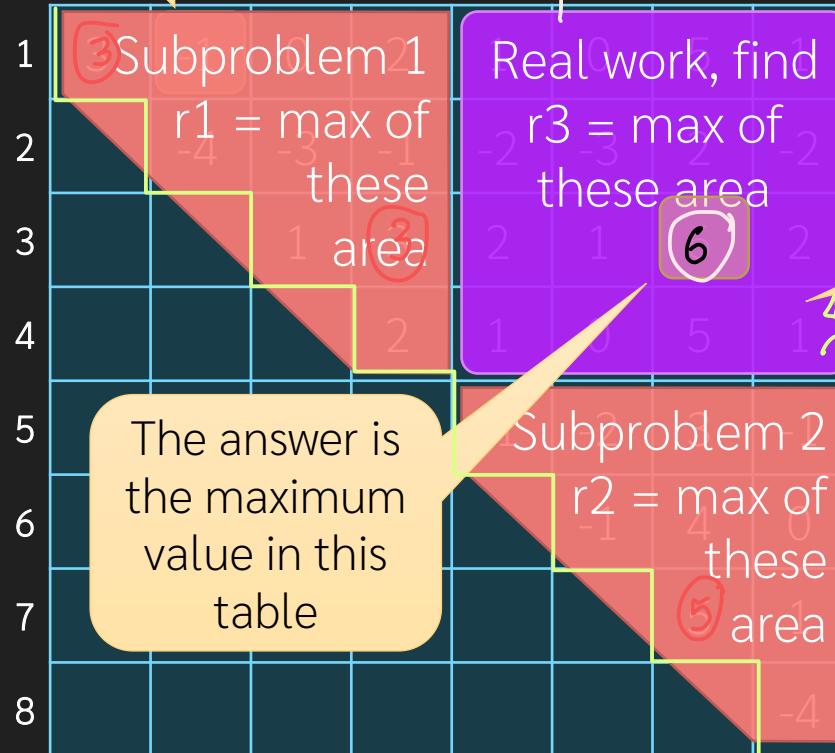

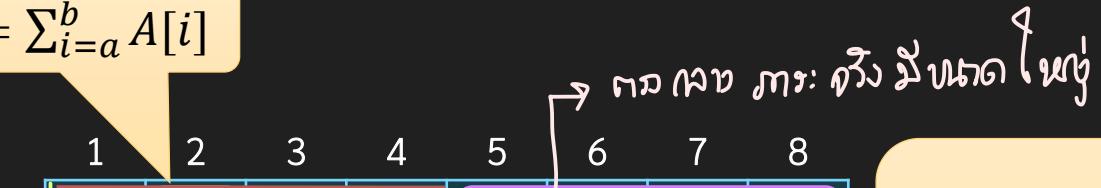

def mss1(A[1..n], start, stop, S)
    if (start == stop)
        return A[start]
    m = (start+stop) / 2

    r1 = mss1(A, start, m)
    r2 = mss1(A, m+1, stop)

    r3 = A[start]
    for p from 1 to m
        for q from m+1 to n
            sum = S[q] - S[p-1]
            if (sum > r3)
                r3 = sum
    return max(r1, r2, r3)
end

```

$$B[a][b] = \sum_{i=a}^b A[i]$$

There are $(n/2)^2 = O(n^2)$ cells in this area
 $T(n) = 2t(n/2) + O(n^2)$

မြတ် B

Actual Version

There are only $n/2 B[*][m]$ and $B[m+1][*]$

We can find max of them in $O(n)$
Hence $T(n) = 2T(n/2)+o(n) = O(n \log n)$

- Reduce real work from $O(n^2)$ to $O(n)$

- Notice that $B[a][b] = B[a][k] + B[k+1][b]$

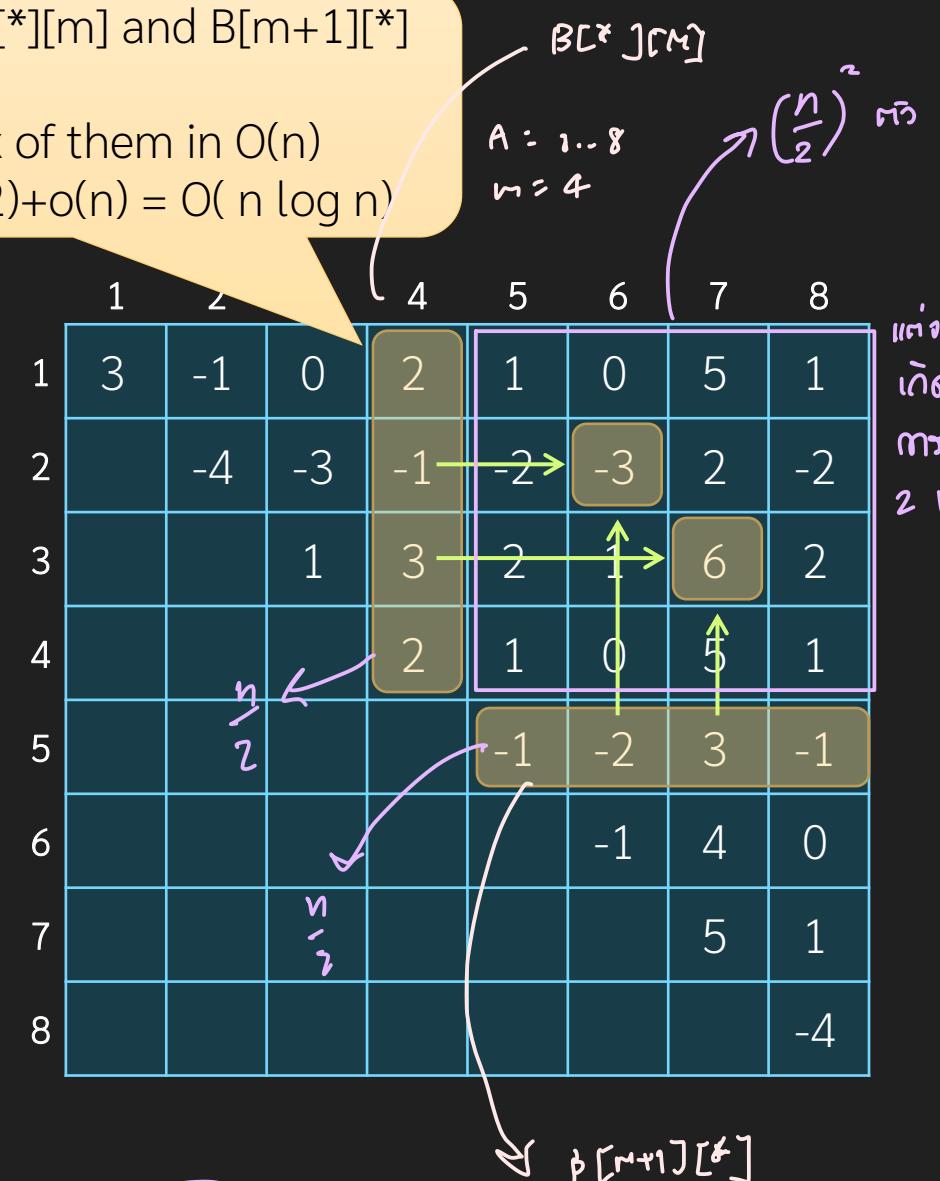

- Real work find max when a is from $1..m$

and $b = m+1..n$

$B[1..m]$
 $B[2..n]$
 \vdots
 $B[m+1..n]$

- If we calculate $B[*][m]$ and $B[m+1][*]$
- Any $B[a][b]$ in these range can be calculated from $B[a][m] + B[m+1][b]$

- Hence $\max_{\substack{1 \leq a \leq m \\ m+1 \leq b \leq n}} B[a][b] = \max_{1 \leq a \leq m} B[a][m] + \max_{m+1 \leq b \leq n} B[m+1][b]$

$B[m+1][*]$

constant
constant

Pseudocode

Strassen's Matrix Multiplication

The Problem

- Invented by Volker Strassen
- Input:
 - two square matrices of the same size
 - $A[1..n][1..n]$ and $B[1..n][1..n]$
- Output:
 - The multiplication of A and B
 - $C = AB$

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix}$$

Square matrix
size n

Naïve Method

- basic $\theta(n^3)$

$$\begin{bmatrix} \textcircled{1} \\ \textcircled{2} \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} \textcircled{1} \\ 0 \end{bmatrix}$$

```
def multi(A[1..n][1..n],B[1..n][1..n])
    let C[1..n][1..n] be a matrix of size n * n
    for i in 1 to n
        for j in 1 to n
            sum = 0
            for k in 1 to n
                sum += a[i][k] * b[k][j];
            C[i][j] = sum
    end
```

$O(n^3)$

ໄດ້ເລີຍເປົ້ອງຕົ້ນ

Block Multiplication

- Divide Matrix into blocks

- $A = \begin{bmatrix} A_{1,1} & A_{1,2} \\ A_{2,1} & A_{2,2} \end{bmatrix}$ ແມ່ນ A ນິຍົມ
Matrix ຈົດວ

- $B = \begin{bmatrix} B_{1,1} & B_{1,2} \\ B_{2,1} & B_{2,2} \end{bmatrix}$

- $C = \begin{bmatrix} C_{1,1} & C_{1,2} \\ C_{2,1} & C_{2,2} \end{bmatrix}$

- Calculate multiplications of blocks

ເກົ່ານຳ ກົດຕາມຮຽນ 2 ຄູ່

- $C_{1,1} = A_{1,1}B_{1,1} + A_{1,2}B_{2,1}$ $(\frac{n}{2})^2$

- $C_{1,2} = A_{1,1}B_{1,2} + A_{1,2}B_{2,2}$

- $C_{2,1} = A_{2,1}B_{1,1} + A_{2,2}B_{2,1}$

- $C_{2,2} = A_{2,1}B_{1,2} + A_{2,2}B_{2,2}$

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix}_{4 \times 4} \quad C = \begin{bmatrix} a_{15} & a_{16} & a_{17} & a_{18} \\ a_{25} & a_{26} & a_{27} & a_{28} \\ a_{35} & a_{36} & a_{37} & a_{38} \\ a_{45} & a_{46} & a_{47} & a_{48} \end{bmatrix}_{4 \times 4}$$

$$B = \begin{bmatrix} a_{51} & a_{52} & a_{53} & a_{54} \\ a_{61} & a_{62} & a_{63} & a_{64} \\ a_{71} & a_{72} & a_{73} & a_{74} \\ a_{81} & a_{82} & a_{83} & a_{84} \end{bmatrix}_{4 \times 4}$$

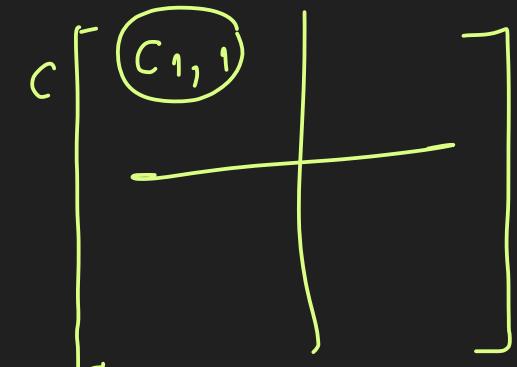

Matrix addition is $O(n^2)$

$$T(n) = 8T(n/2) + O(n^2)$$

$$= O(n^3)$$

Strassen's Algorithm

គណនោ matrix ទៅ បិទបិន្ទុនីង
ទូយ Matrix $A \cdot B$

- Compute $M_1 \dots M_7$

$$\left. \begin{array}{l} \bullet M_1 = (A_{1,1} + A_{2,2})(B_{1,1} + B_{2,2}) \\ \bullet M_2 = (A_{2,1} + A_{2,2})(B_{1,1}) \\ \bullet M_3 = (A_{1,1})(B_{1,2} - B_{2,2}) \\ \bullet M_4 = (A_{2,2})(B_{2,1} - B_{1,1}) \\ \bullet M_5 = (A_{1,1} + A_{1,2})(B_{2,2}) \\ \bullet M_6 = (A_{2,1} - A_{1,1})(B_{1,1} + B_{1,2}) \\ \bullet M_7 = (A_{1,2} - A_{2,2})(B_{2,1} + B_{2,2}) \end{array} \right\}$$

- Note that each M can be computed by one single multiplication of $n/2 * n/2$ matrices, with 1 or 2 addition of a matrix

$$\begin{aligned} M_1 &= (A_{1,1}B_{1,1} + A_{1,2}B_{2,1} + A_{2,1}B_{1,2} + A_{2,2}B_{2,2}) \\ M_4 &= A_{2,2}B_{2,1} - A_{2,2}B_{1,1} \\ M_5 &= A_{1,1}B_{2,2} + A_{1,2}B_{2,2} \\ M_7 &= (A_{1,2}B_{2,1} + A_{1,2}B_{2,2} - A_{2,2}B_{2,1} - A_{2,2}B_{2,2}) \end{aligned}$$

ការគំចែកលើ

- The result can be computed as

$$\bullet C_{1,1} = M_1 + M_4 - M_5 + M_7$$

$$\bullet C_{1,2} = M_3 + M_5$$

$$\bullet C_{2,1} = M_2 + M_4$$

$$\bullet C_{2,2} = M_1 + M_2 + M_3 + M_6$$

- Total of $\boxed{7}$ matrix multiplications and

$$\boxed{18} \text{ matrix } \underline{\text{addition}}$$

វិនក់ ទូន 8 នាម 4

Analysis

$$T(n) = 7T(n/2) + O(n^2)$$

- Using Master's method
- $a = 7, b = 2, f(n) = O(n^2)$
 - $c = \log_2 7 \approx 2.807$
- Hence, $T(n) = O(n^{2.807})$

ଏହା $O(n^3)$ କିମ୍ବା n^2

$\nearrow O(n^2)$

Year	Algorithm	Complexity
1969	Strassen	$O(n^{2.807})$
1987	Coppersmith–Winograd	$O(n^{2.375})$ କିମ୍ବା
2010	Improved CW (by Andrew Stothers)	$O(n^{2.374})$
2011	Further improvement of CW (by Virginia Vassilevska Williams)	$O(n^{2.3728642})$
2014	Improve over Williams' (by François Le Gall)	$O(n^{2.3728639})$

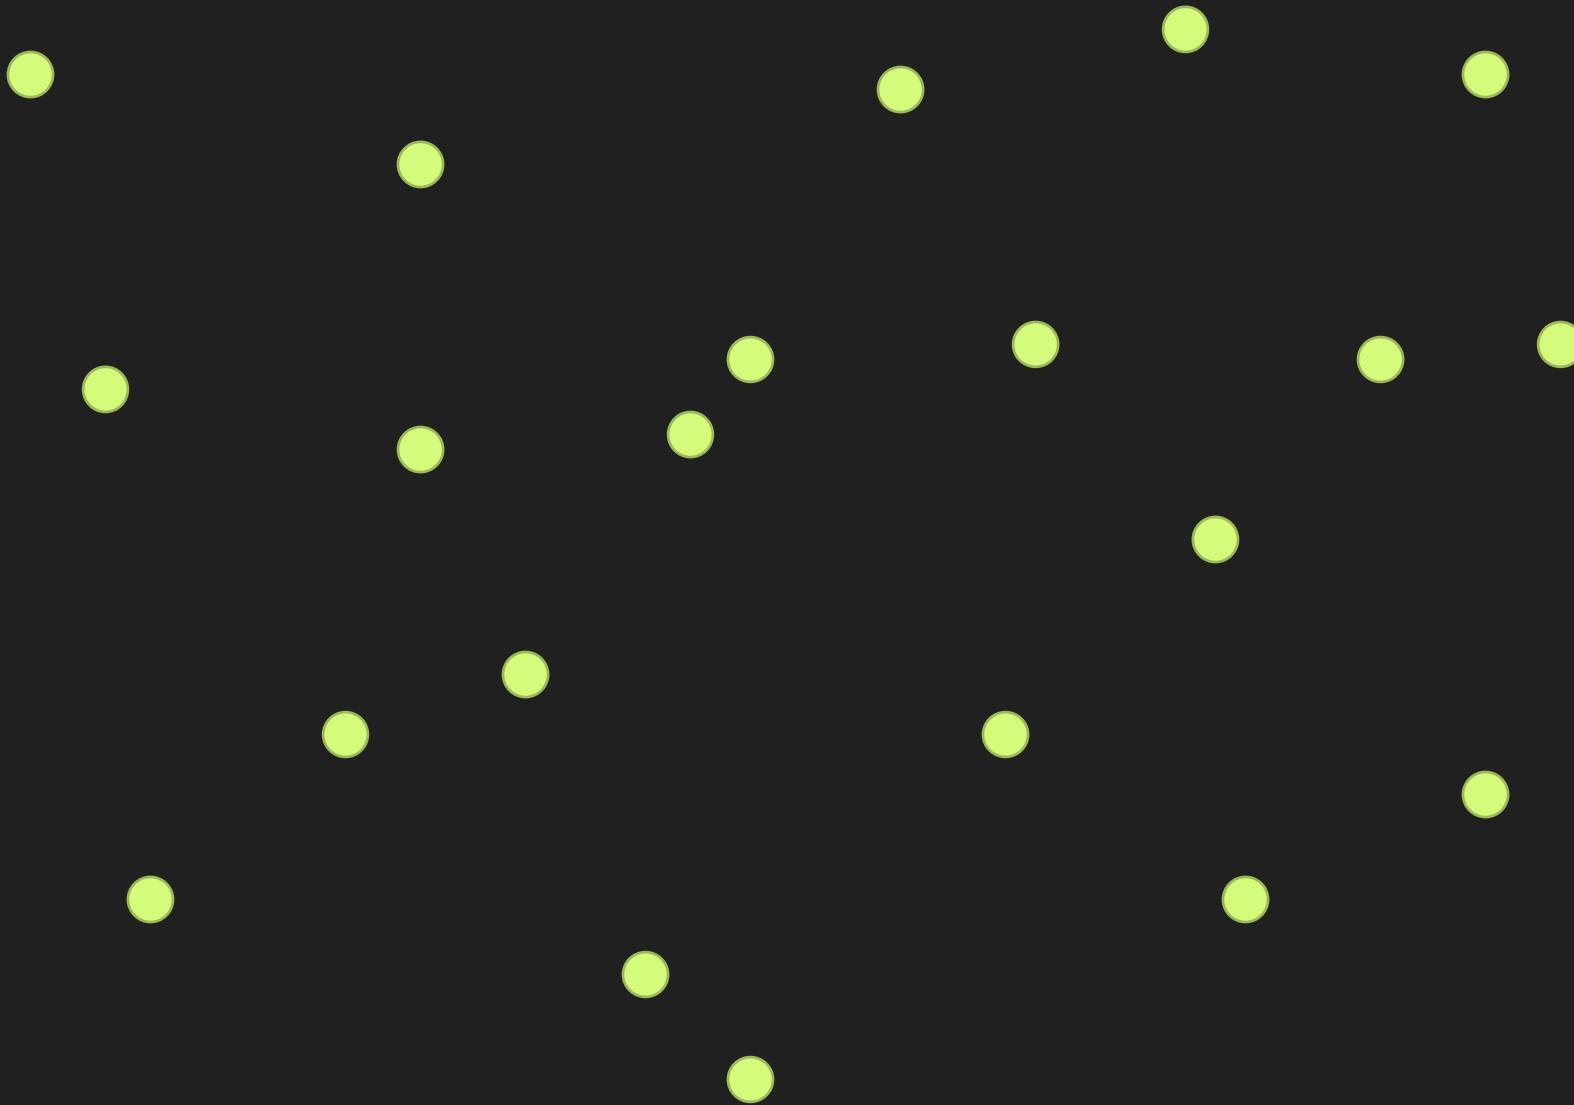

କିମ୍ବା $O(n^3)$ କିମ୍ବା

Closest Pair

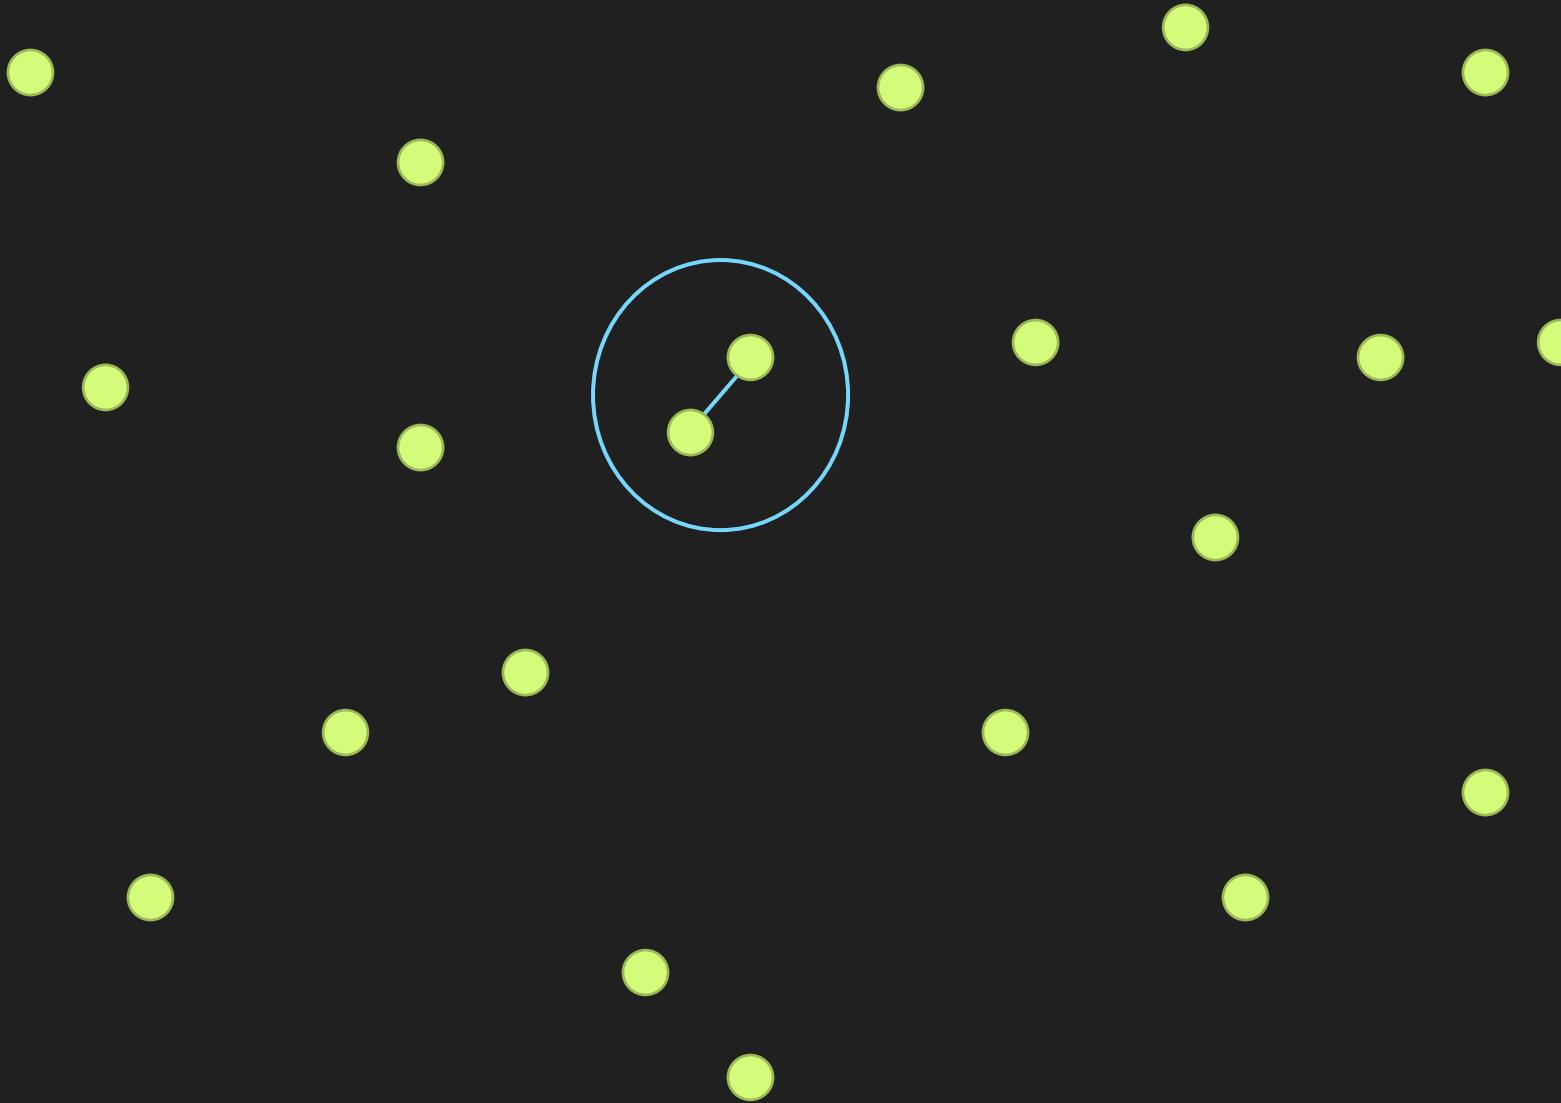

The Problem

- Input:
 - Coordinates of n points in 2D
 - $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ අනුකූල මුදලාගාර සංඛ්‍යා පිළිබඳ නැත්තු ඇති පිටත පිළිබඳ මුදලාගාර
- Output
 - A pair of points from the given set
 - $(x_a, y_a), (x_b, y_b)$ $1 \leq a, b \leq n$
 - Such that the distance between the points is minimal

Input Example

Output Example

The Naïve Approach

- Try all possible pairs of points
 - There are $n(n+1)/2$ pairs
 - Compute the distance of each pair
 - Takes $\Theta(1)$ for each pair
- In total, it is $\Theta(n^2)$

DC approach

- What if we know the solution of the smaller problem
 - What if we know the Closest Pair of half of the points?
 - Which half?

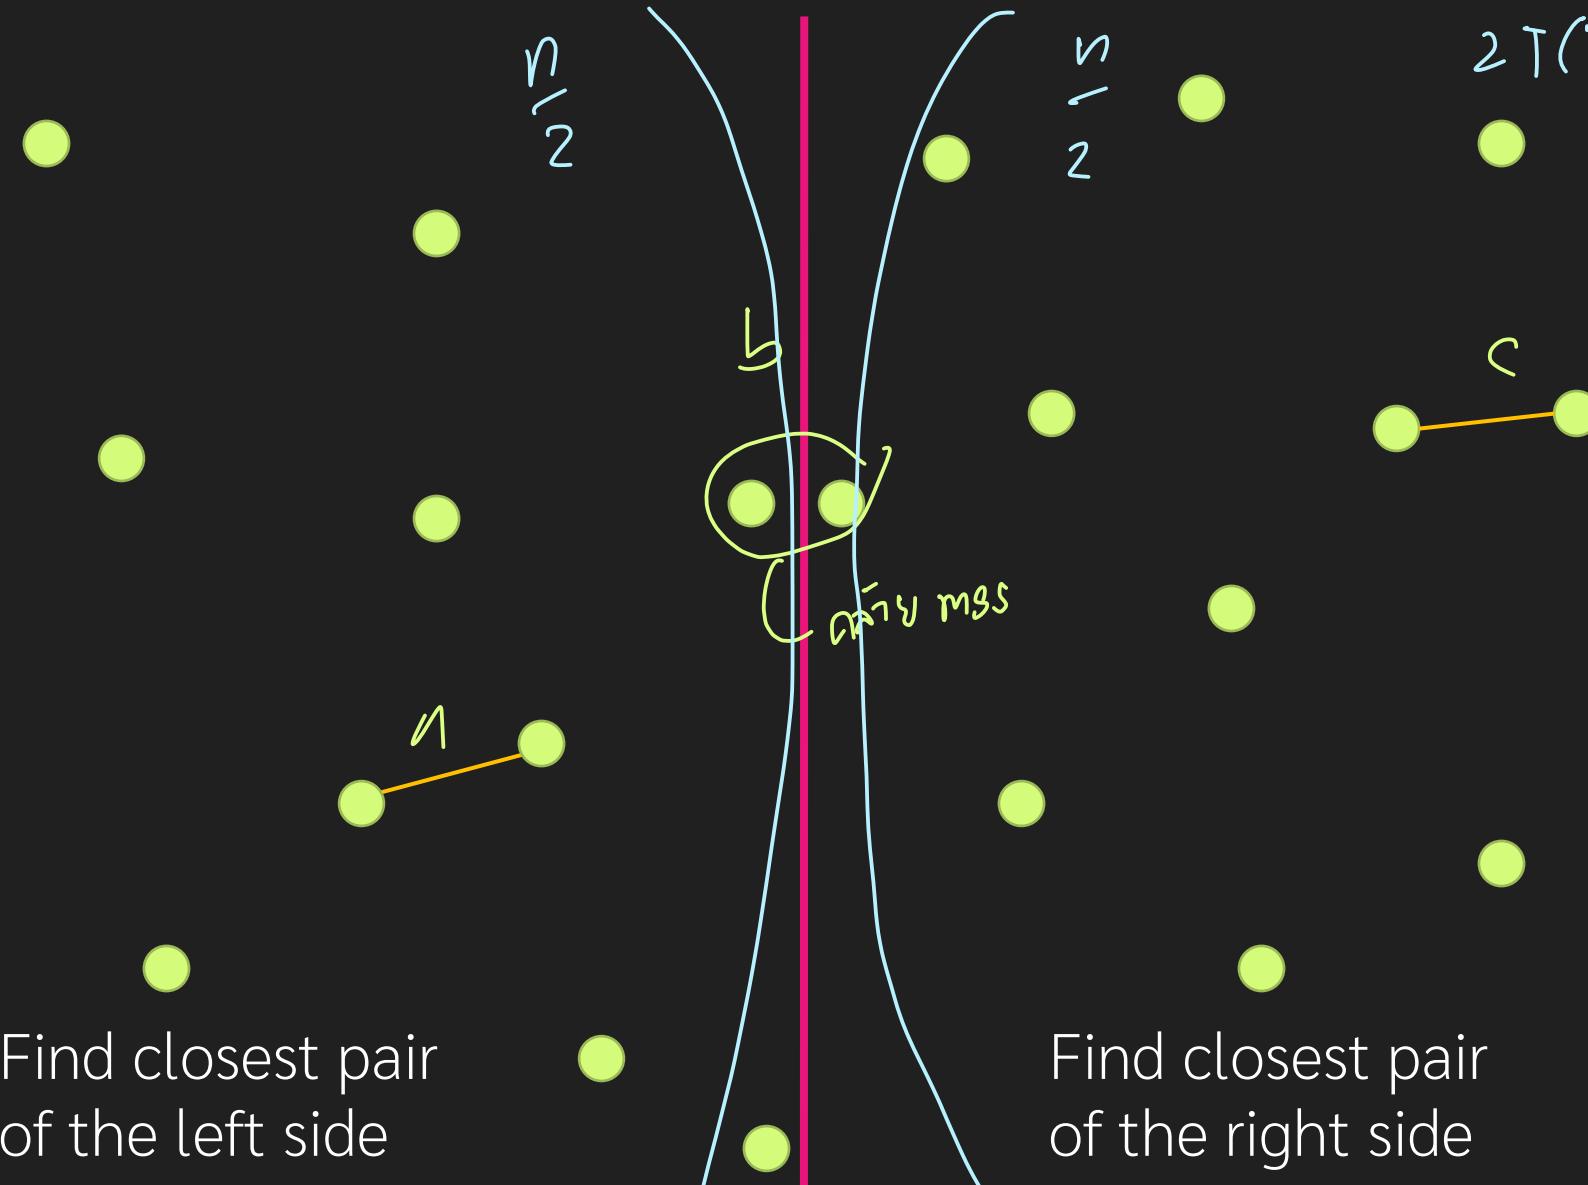

$$\begin{aligned} T(n) &:= 2T\left(\frac{n}{2}\right) + O(n) \\ &= \tilde{T}(n \lg n) \end{aligned}$$

Divide by X axis

ແບ່ງໂຕຢູ່ຈຳກັນ X

$$O\left(\frac{n}{2}^2\right) \rightarrow O(n^2)$$

$$2T\left(\frac{n}{2}\right) + O(n^2)$$

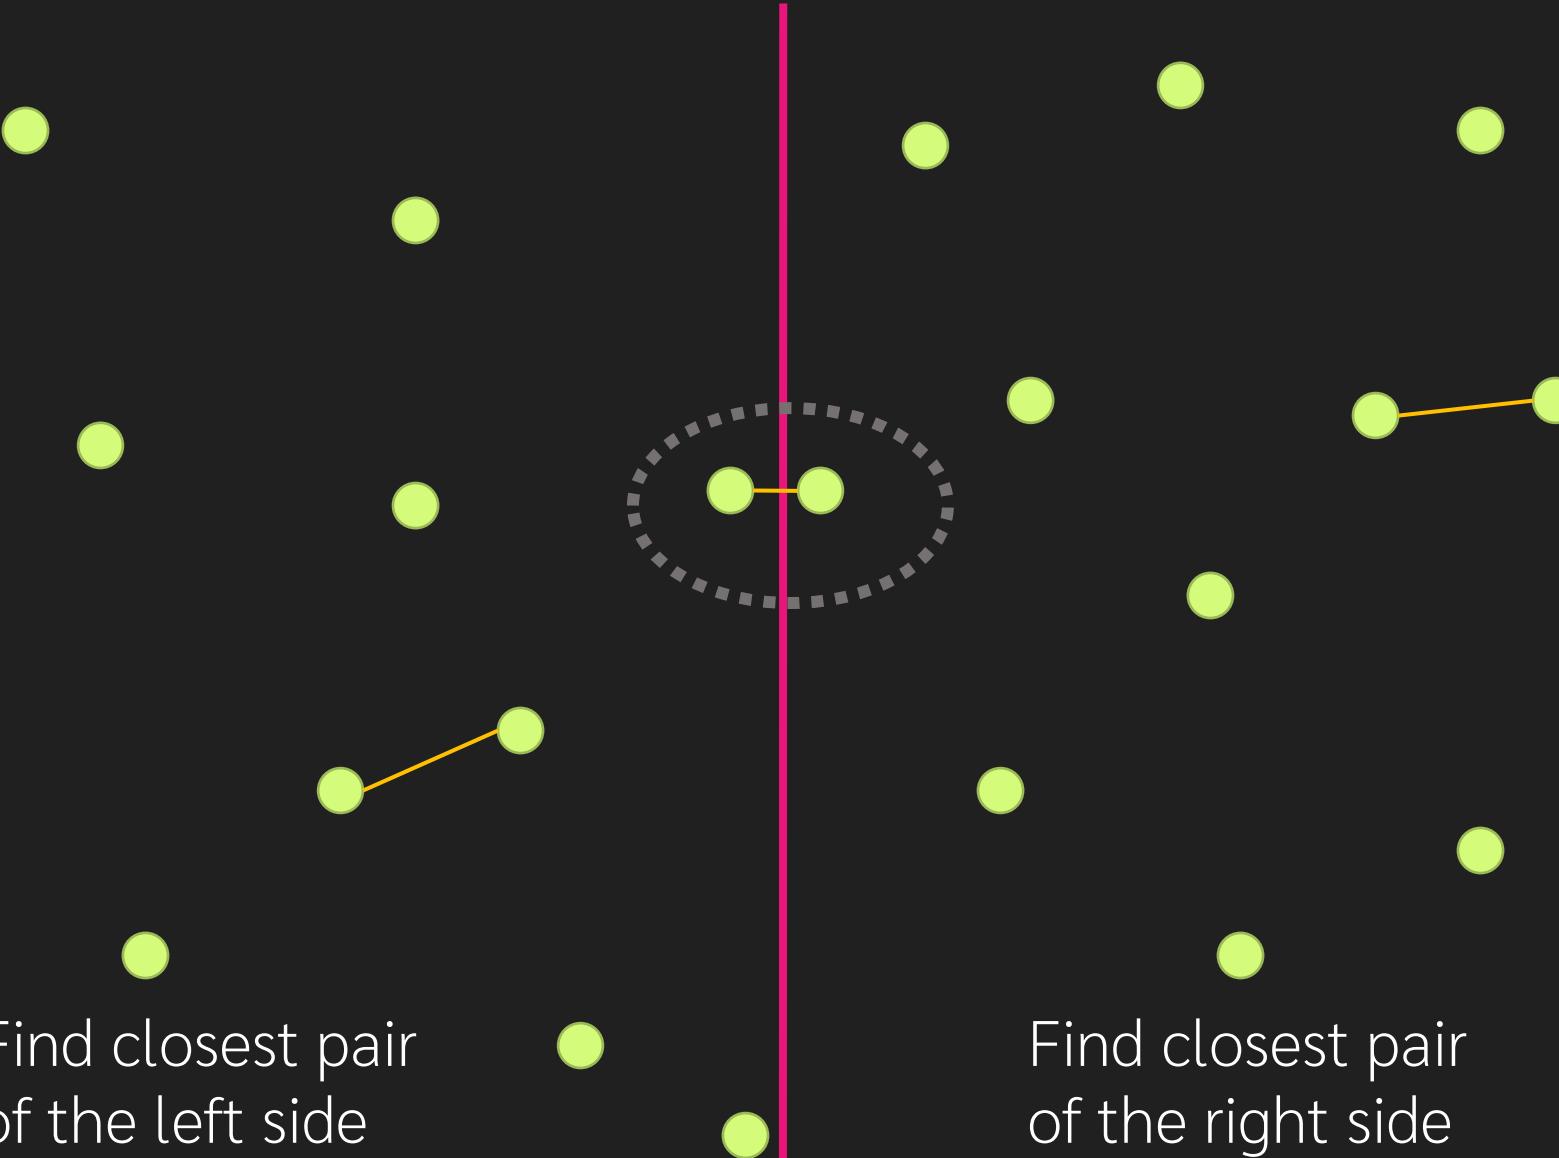

Conquer

ແມ່ນທີ່ກົດຖຸດັງ → ຂົດປາກູ

- Similar to the MSS problem, solutions of the subproblems do not cover every possible pair of points
 - Missing the pairs that “span” over the boundary
 - There are $(n/2)^2$ such pairs, if we simply consider everything, it would be $O(n^2)$, still quadratic running time
 - To get better complexity, we something better than $O(n^2)$ for the real work

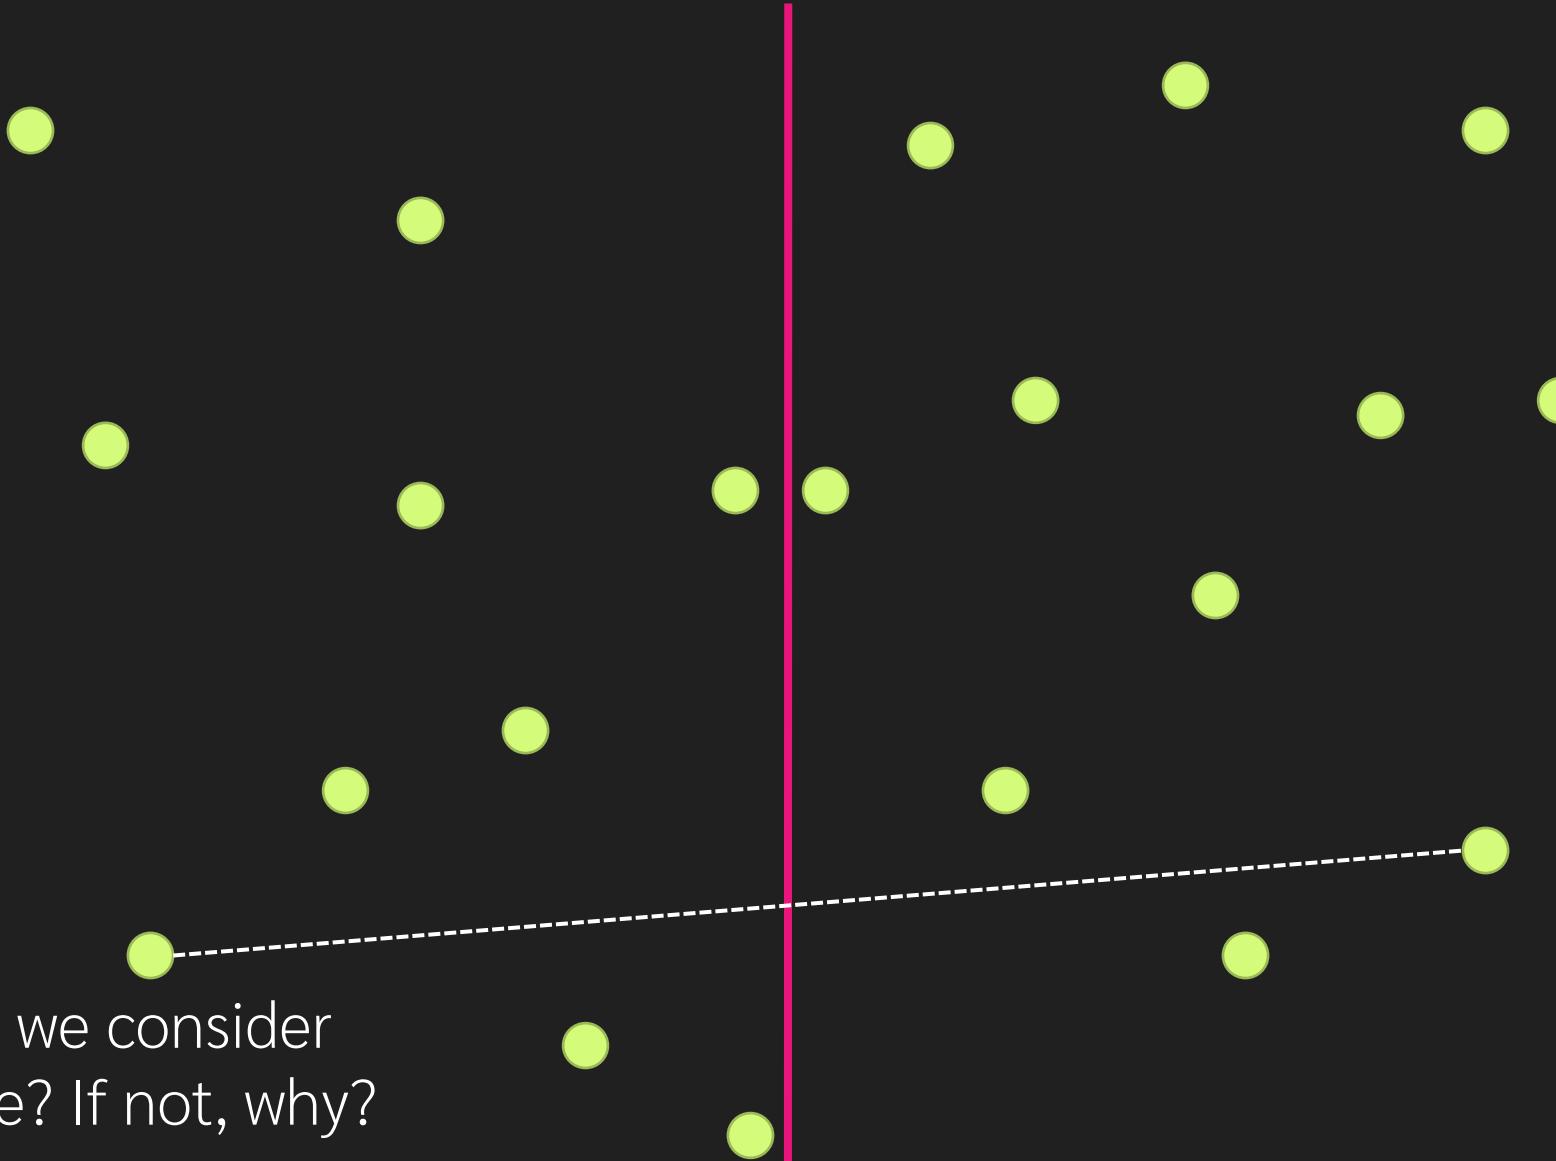

Divide by X axis

Find Closest Spanning Pair

- Should consider only the nearer pairs
 - Skip pairs whose distance is definitely larger than **b**
 - Should not consider the pair on the far left with that on the far right

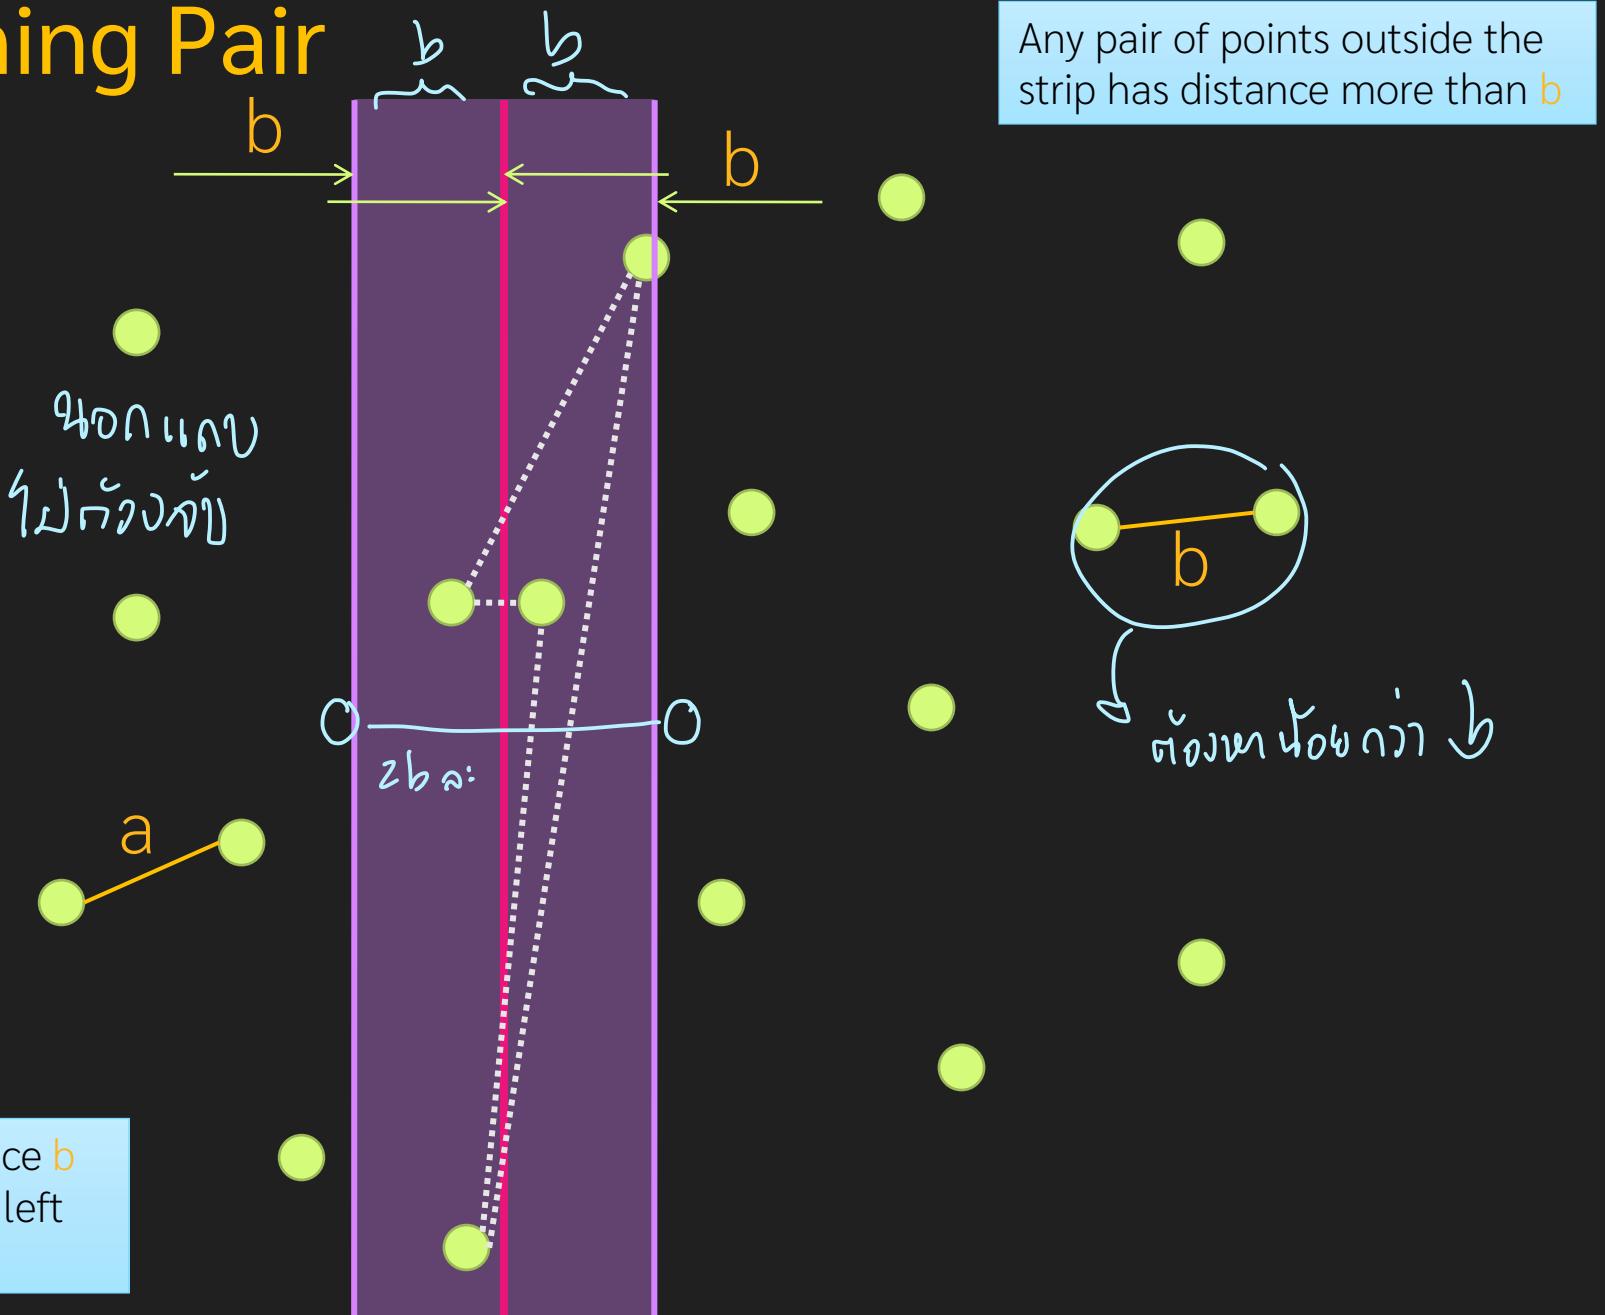

Find Closest Spanning Pair

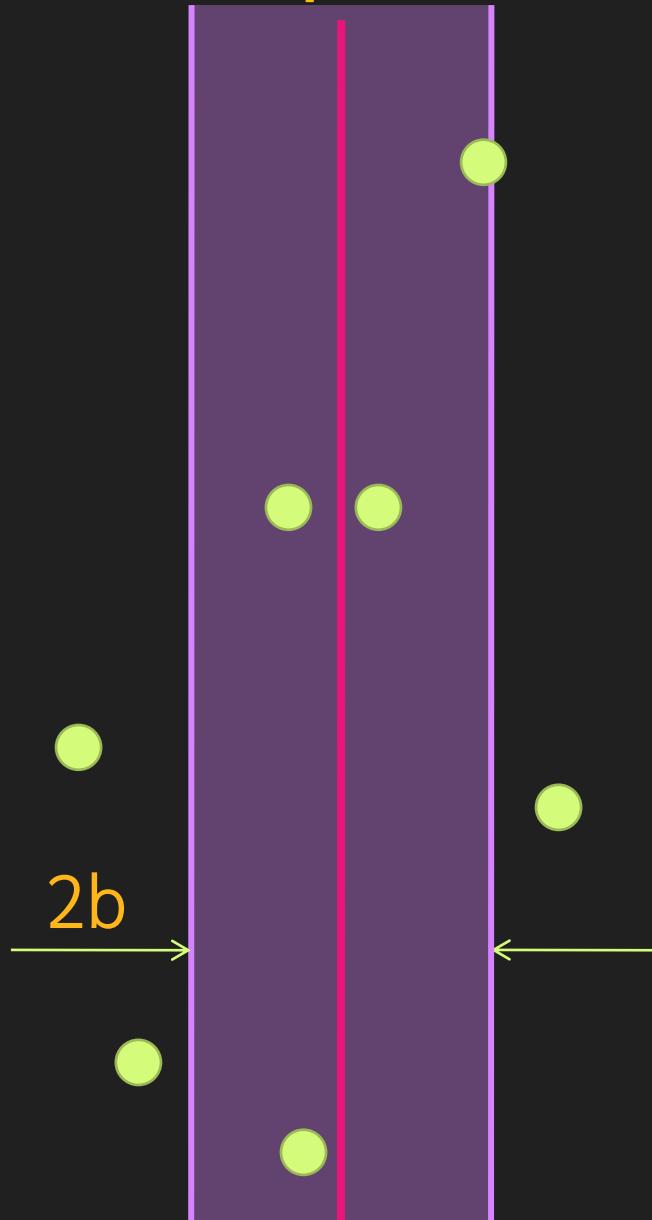

Possible Spanning Pair

- Let a be the minimum distance of the left subproblem
- Let b be the minimum distance of the right subproblem
- Assume $b < a$

Consider only pairs in the strip of distance b from the division line, one point on the left side, another point from the right side

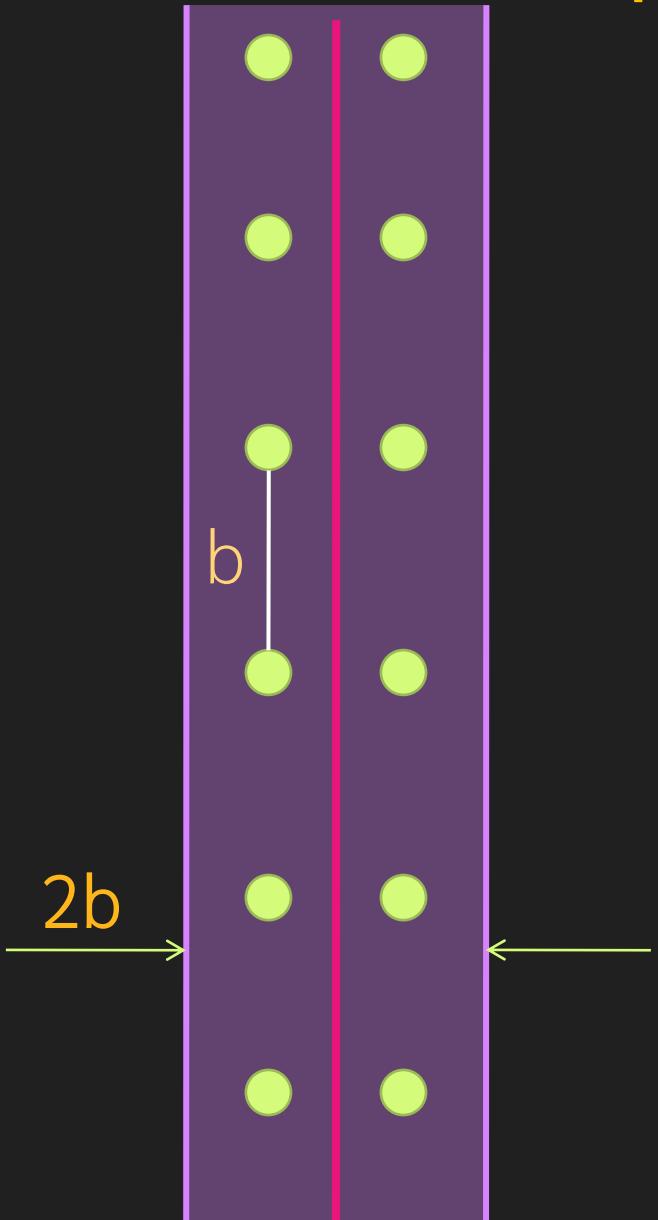

Point in Strips

- How many pairs in the strip?
 - Can it be more than n ?

Pairs of Point in Strips can be is $O(N^2)$

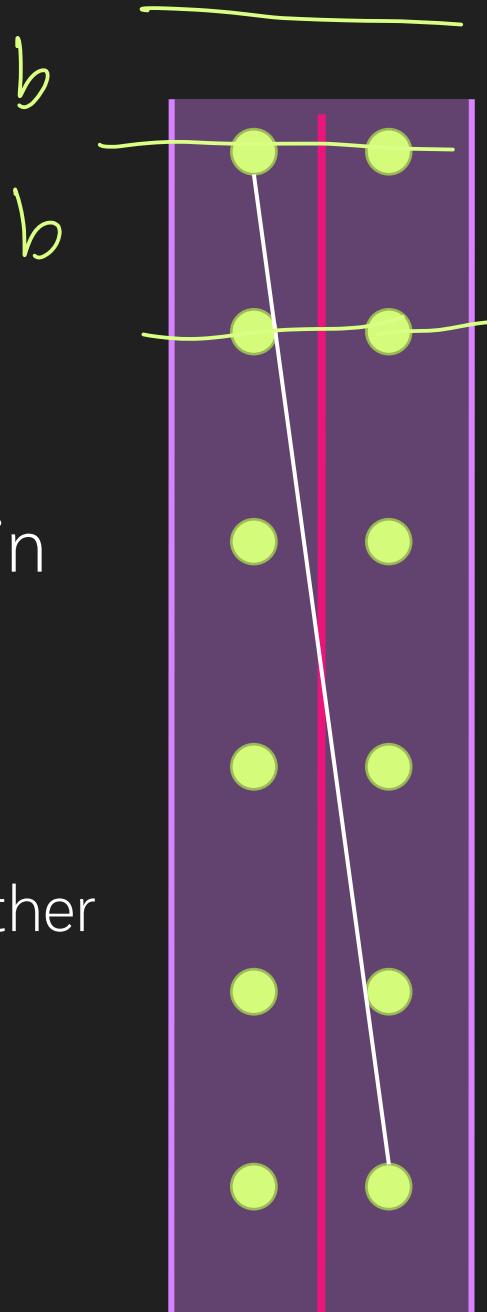

- Bad news
 - There can be as much as $n/2$ points on each side
 - Consider a set of vertically aligned point
 - Each are b unit apart
 - So, all points will be in the strip of $2b$ width
- The problem
 - If we check every pair of points, we still stuck with $O(n^2)$ time

କୁହାନା ଯ ଦୟ ଗୁରୁମ୍ଭ

The Solution

- Think Vertically
- Do we have to check for every pair in the strip?
 - No, just like the case of X-axis
 - Don't consider pairs that is surely further than b

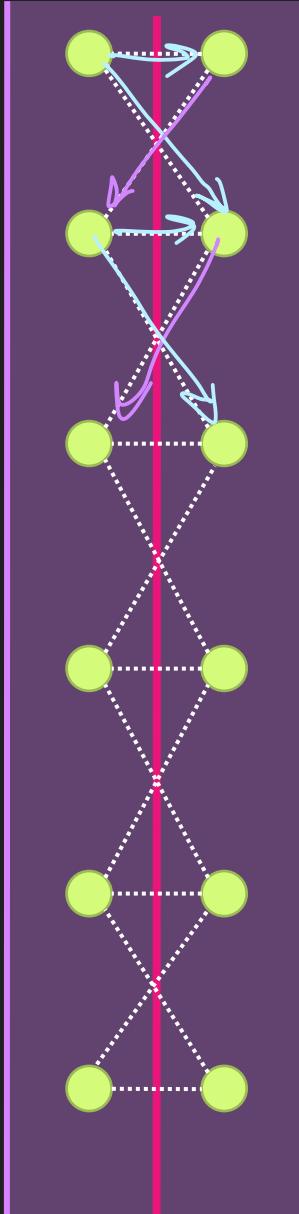

Spanning Pair to be considered

- X-value must be in the strip
 - Check only point in the left side to point in the right side
- Y-value
 - For points in the strip
 - Check only point whose y-value is not more than **b** unit apart

រាយការណ៍កំណត់ពេលវេលាដែល

ស្ថិតិយកម្មគោរក

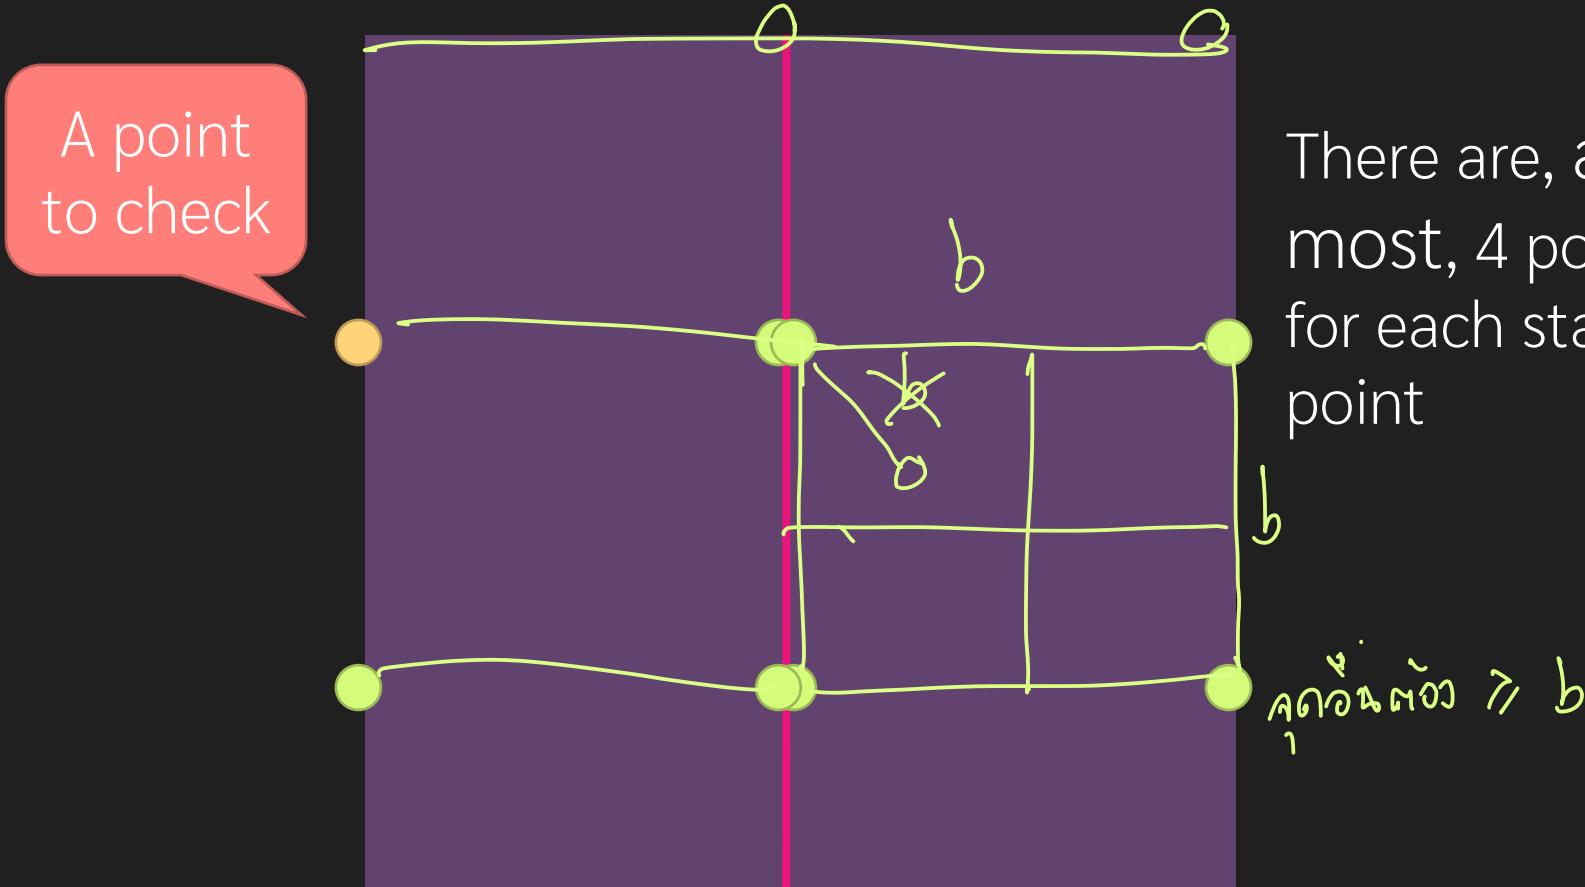

Question is still remains

$$T(n) = 2T\left(\frac{n}{2}\right) + O(n)$$

- How many pair to be checked?

$$O(n \lg n)$$

$$CP(P_{x\text{sort}}, P_{y\text{sort}})$$

There are, at most, 4 points for each starting point

ក្នុងពេលវេលា > b

Implementation Detail

గ్రాఫిక్స్ టూల్స్ రూల్స్ యు లోన్

- For each point on one side, if we have to loops over every points on the other side to test whether the Y-value falls within range, it will still take $O(n)$
 - However, if the points are sorted by Y-value, we can scan from top to bottom and stop when difference of Y-value exceeds b

Let $L[1..p]$ be points on the left strip, sorted by y-value
Let $R[1..q]$ be points on the right strip, sorted by y-value
Let b be the width of the strip

```
result = (L[1], R[1])
min = distance(L[1], R[1])
right_idx = 1
for left_idx = 1 to p
    while right_idx < q && L[left_idx].y + b < R[right_idx].y
        d = distance(L[left_idx], R[right_idx])
        if d < min
            result = (left_idx, right_idx)
        right_idx = right_idx + 1
#dit again, starting with right side
```

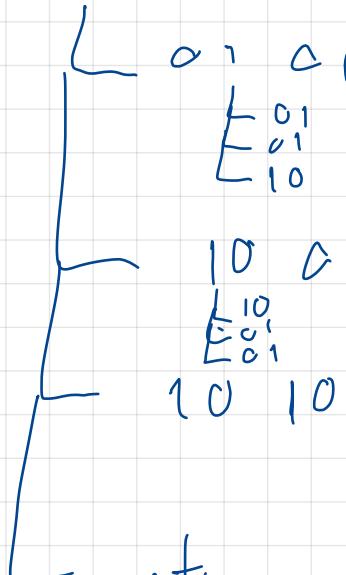

If we sort every time we do recursive call,
Real work will be $O(n \lg n)$

That would result in $O(n \lg^2 n)$

Better Approach

- Point must be sorted in x-value so that dividing can be done in $O(1)$
- Point must also be sorted in y-value, so that we can stop checking points in the strip
- Sorting points only at the beginning
 - Both sorting can be done in $O(n \lg n)$ at the preprocess step
- Data is passed to the function in two separated list, one is x-sorted another one is y-sorted
 - When divide, both list are separated
 - Can be done in $O(n)$
